Mr. Montsinger, in his discussion, clearly points out his difference of opinion as to the characteristics of insulation deterioration. He is not, however, entirely consistent in his criticisms. He refers to Figure 5 as indicating that insulation shows a continuous decrease in tensile strength, even when protected by nitrogen. In that case, the introduction of varnish-treated material is shown to be the cause, and even an inert atmosphere will not provide protection when such materials are used. Mr. Clark, in his discussion, clearly took this point into consideration.

Mr. Montsinger has seen fit to replot the data of Figure 1 on semilogarithmic paper. He, however, first assumes that the data should be represented by straight lines on semilogarithmic paper. If that assumption were not made, curves could equally well be shown as flattening out in the period between six to ten weeks and results nearly constant after 10 to 15 weeks.

In considering Mr. Clark's discussion, one might think that we recommended temperatures in the neighborhood of 135 degrees centigrade for operation. This is not true. Within definite limits, excluding oxygen does result in a higher mechanical strength of insulation for a given time and temperature. It is generally well recognized that thermal decomposition of cellulose takes place at a temperature above 125 degrees centigrade, and the advantage of an inert atmosphere would be partially lost if operative temperatures in this range were continuously employed.

Table II

Temperature Limits	Oxidation	Thermal Decomposition
Clark	75–100	Above 100
Sloat-Vogel	75–120	Above 120

With respect to the discussion regarding the effectiveness of acids, additional tests made at the same time as those represented show that Fuller board is affected by acids. It might be pointed out in all cases the acids referred to contain some peroxides. The peroxides are the detrimental agents, as they cause cellulose deterioration. However, it is quite well accepted that the acids are a measurement of the peroxides present.

With respect to Mr. Clark's discussion regarding the mechanical stability of cellulose insulation as affected by oxygen, one might be led to believe that the rate of insulation deterioration at the lower temperatures is so slight that it would be demonstrated with great difficulty, and that there is less and less difference as the temperatures become higher. One of the best evidences to the contrary is the comparison between Figure 1 and Figure 11 of the paper. In Figure 1 at 105 degrees centigrade, the insulation strength seems to be about 70 per cent of its original value after eighteen weeks at 105 degrees centigrade, whereas, with air present it was down to 35 per cent and decreasing rapidly. There is, however, some agreement with Mr. Clark, after all, in the results of our tests. We agree on the types of cellulose deterioration, but not in the degrees of temperature at which the types of deterioration take place as shown in Table II of this discussion.

It should be noted, that there is no sharp line of demarcation. Both effects overlap to

some extent. Temperature limits in Table II should be considered as those limits within which either oxidation or thermal decomposition are predominate factors.

Factors Affecting the Mechanical Deterioration of Cellulose Insulation

Discussion and author's closure of paper 42-98 by F. M. Clark, presented at the AIEE summer convention, Chicago, Ill., June 22–26, 1942, and published in AIEE TRANSACTIONS, 1942, October section, pages 742–9.

V. M. Montsinger (General Electric Company, Pittsfield, Mass.): F. M. Clark's paper adds a definite milestone in determining the effect of temperature and moisture on the aging of insulation. For several years we have been in need of more exact data on how the higher temperatures affect the rate of aging of cellulose insulation. While I have used the eight-degree rule in deriving short-time overloads where the temperatures were considerably in excess of 110 to 120 degrees centigrade, I had no definite proof that it held for the higher temperatures. Consequently, I am considerably relieved to learn that the eight-degree rule holds up to 200 degrees centigrade.

Of course, it should not be overlooked that Mr. Clark finds that for temperatures in the order of 90 degrees centigrade to 105 degrees centigrade, a rule less than eight degrees holds (in the order of three to six degrees), and for lower temperatures a still lower rule, as low as two degrees, holds.

Based on Mr. Clark's data, the eight-degree rule should be used in estimating short-time overloads where the hottest spot temperature is in excess of approximately 110 degrees to 115 degrees centigrade, and approximately a five-degree rule when estimating the effect of temperatures in the neighborhood of 90 degrees to 100 degrees centigrade on the life of transformers. There is one very important way in which the five-degree rule can be used, namely, to see whether it is economical to increase the temperature rise of transformers above 55 degrees centigrade. For example: by the five-degree rule, the life of a 60 degrees centigrade rise transformer is half that of a 55 degrees centigrade rise transformer. The extra capacity gained when increasing the average rise from 55 degrees centigrade to 60 degrees centigrade, is in the order of six to seven per cent, and the gain in cost is in the order of three to four per cent. Consequently, by this process of reasoning, we save an initial investment of three to four per cent for a transformer having one-half the life. The initial saving in cost does not sound like a good economical proposition.

There is one very important point that has been settled by these tests, namely, that the effects of several overloads on the life of a transformer, are additive. This has generally been assumed in the past, but we had no definite proof that these assumptions were correct.

Mr. Clark's discovery of the important role that water content plays in the rate of aging also explains why my early tests showed that the insulation aged faster in mineral oil than in air—oven aged. Since the importance of keeping the insulations perfectly dry was not realized, the samples no doubt picked up considerable water between the drying period and the starting of the aging tests. The moisture that was picked up previous to the oven- or air-aged samples naturally was driven off immediately, while the oil-immersed samples retained their moisture to a certain extent.

To quote from my 1930 AIEE paper on "Loading Transformers by Temperature":

> "No completely satisfactory explanation has ever been given for this shorter life of insulation (aged) in oil than in air, though it has been suggested that it may be due either to the oil softening the fibers, or the acids in the oil attacking the fibers. This is a good subject for a physicist to study."

While this paper does not show comparative aging in air and in oil, such tests have been made under closely controlled moisture conditions, and no material difference was found in the rate of aging. Apparently this question has been cleared up, and we can no longer claim that the life of cellulose is longer in air than in properly protected oil, provided, of course, that the insulation is dry.

Herman Halperin (Commonwealth Edison Company, Chicago, Ill.): I have followed with interest Mr. Clark's series of papers, which always contain a large amount of useful information. Figure 6 is of special interest, but it seems that some caution should be used in applying these data. The figure indicates that toward the end of the life in the range of 75 to 100 degrees centigrade, an increase in temperature of 2 or 2.4 degrees cuts the remaining life in half, and the conclusion may be drawn that a slight temperature increase is a serious matter. It should be noted, however, that this conclusion is based on values extrapolated from about 100 weeks to 2,000,000 or 5,000,000 weeks and from about 25 per cent reduction in strength to 100 per cent reduction in strength. It is quite possible that actually the slope of the 75-degree curves in Figures 3 and 4 might be quite different for long durations or, in other words, that the total life is quite different from the extrapolated values of 2,000,000 or 5,000,000 weeks. Such a change would, of course, affect the relation between rate of deterioration and temperature increase.

From a practical standpoint the upper portion of Figure 6 is relatively most important, that is, down to 50 per cent of the initial strength. The average for the first 50 per cent of the mechanical life consumption of the temperature increase to double the rate of deterioration ranges from about six to ten degrees centigrade which, for practical purposes, agrees quite well with Montsinger's eight-degree rule.

Figure 4 of Mr. Clark's paper shows much greater deterioration than indicated in oven-aging tests in Chicago of sealed cable samples, which are described in my AIEE paper on "Load Rating of Cable—II."[1] As in both Mr. Clark's and the Chicago tests, the insulation was vacuum dried, and oxygen was excluded, the tests should be expected to be comparable. Figure 4 of Mr. Clark's paper shows for one year at 100 degrees centigrade a reduction in strength of about 35 per cent while the same test period in Chicago produced for a large number of samples an average reduction in strength of four per cent and a maximum reduction of 19 per cent. To obtain a 50 per cent reduction in mechanical strength in one year, a temperature of about 102 degrees is required, according to Mr. Clark's tests, while the tests on short cable samples and on large trial field cable installations in Chicago indicate that about 120 degrees is required. Possibly, the difference in cable oils and transformer oils had some effect on the large resultant difference of 18 degrees centigrade, but that explanation does not seem adequate.

The information on the effect of moisture and of volatile acidic products upon the rate of deterioration is of considerable interest. The possible importance of the effect of moisture and volatile products upon oil-impregnated insulation was early recognized in the research project on insulating oils and cable saturants at the Massachusetts Institute of Technology, and for this reason these studies were made in a closed system which allowed retention of moisture and volatiles if desired. However, no concrete data, especially on paper strength such as given by Mr. Clark, were available. From a practical standpoint, I am glad to see additional evidence emphasizing the importance of keeping the content of moisture and acids in impregnated insulation to a minimum.

Mr. Clark's discussion of the effect of oxygen may create the impression that, above 120 degrees centigrade, oxidation becomes less pronounced while, if I understand correctly, oxidation above 120 degrees becomes less important only in comparison with the rapidly increasing pyrochemical decomposition.

J. G. Ford (Westinghouse Electric and Manufacturing Company, Sharon, Pa.): I am very much interested in the paper of F. M. Clark on the subject of "Factors Affecting the Mechanical Deterioration of Cellulose Insulation." The paper indicates that he has done considerable detail work on this study of a problem which is very important to the electrical industry. There are several points which come to mind which I would like to discuss briefly.

In the method used by Mr. Clark as described in his paper the initial samples of 0.003 manila paper were conditioned at 65 per cent relative humidity at 70 degrees Fahrenheit. I note that the oil impregnated papers are tested immediately after being taken from the oil sample. This brings up the question as to the dryness of samples and the effect of the oil on the tensile strength on which aging tests have been made. It would appear that it would be desirable to test the samples all at the same water content so that the values obtained would be representative of the actual change in tensile strength. This, of course, would involve extracting the oil from the paper and subsequently humidifying under the same condition.

I note that practically all of the work that has been done on the subject of aging of cellulose insulation as used in transformers, involves tensile-strength measurements on the insulation. Personally I do not believe that deterioration in tensile strength tells the complete story, and I would suggest that compression strength as well as shear strength would be of even greater importance, particularly, since the short-circuit stresses on transformers subject the insulation to both compression and shear rather than tension. Based on actual tensile strength on old transformers we have examined, it would appear that such transformers would not stand any short-circuit tests. However, such transformers have been tested and found to stand up, again indicating that the insulation is more liable to fail by compression rather than tension. Of course, it is understood that lower tensile strength would also indicate lower compression strength of insulation, but this may not be a direct relationship. Mr. Clark has made a considerable number of tests to demonstrate the effects of decomposition products of cellulose on the deterioration of the cellulose. I think we all agree that decomposition products are detrimental and are a factor in the life of a transformer. However, I believe that the type of test Mr. Clark has made exaggerates the effect of decomposition products inasmuch as the cellulose is heated in a sealed tube in which all the components are at the same temperature, whereas in a transformer the winding temperature is always higher than the temperature of the oil and surrounding temperatures, and generally in any transformer there is a cool zone which will allow for the condensation of these products, thus reducing the effects. We have recognized the effects of reaction products from varnish and other materials as being also in the same category as decomposition products of the cellulose itself and have attempted to eliminate such products in the present design of the transformer. In many cases we have substituted varnish-treated materials with plain paper, and, where varnishes are used, we have adopted synthetic, low-acid-type varnishes, so as to keep the acidity at a minimum value.

I believe the study of insulation deterioration in transformers is very important and merits further study, but I am convinced that we should have compression and shearing strengths as well as tensile strength, and also that such laboratory information should be backed up by actual tests on aged transformers.

R. W. Atkinson (General Cable Corporation, Bayonne, N. J.): Mr. Clark's extensive data concerning deterioration of cellulose insulation at high temperature and his analysis of these data mark a great advancement in this important field. His quantitative information on the effect on deterioration at various temperatures of moisture and oxygen, singly or together, go far beyond anything previously available.

Over the past few years various manufacturers have been studying the deterioration of varnished cloth insulation at various temperatures. The very great increase of deterioration rate produced by the presence of small quantities of water has been found there also. Furthermore it has been found that this greater mechanical deterioration has been accompanied by a large increase in dielectric power factor. These results apply to sealed samples. In samples open to the air the moisture is driven off at the aging temperatures, and its effect becomes unimportant.

F. M. Clark: The study of the aging of any organic material is extremely difficult, because the products of the chemical changes involved are frequently extremely effective in determining the rate of subsequent deterioration. This has led to the generally accepted idea that the best way to study the deterioration of an organic product whether it be an automobile tire or mineral oil is to reproduce as nearly as possible the conditions of actual commercial use. This is true of cellulose insulation. Attempts to reproduce the conditions of transformer service, however, have resulted in a variety of test data which have been frequently in conflict and have been of doubtful value because of the difficulty of controlling the conditions of the test run. In general, therefore, the laboratory tests on the deterioration have been found to be most acceptable when some sacrifice has been made in the desire to reproduce commercial conditions in favor of the necessity of obtaining accurate test control. This has been done in the various studies both in this country and abroad in the testing of mineral oil and cellulose. Test results obtained in such a way have invariably been found to represent more severe deterioration than would be expected from service data but with proper consideration to the basic principles involved, such studies have promoted progress toward the goal of greater chemical and mechanical stability.

Mr. Halperin finds that the laboratory data which I have presented indicate a more severe deterioration than he has observed in cable studies. The test set-up which I have used was intended to produce data applicable to transformer use. Other studies which we have made indicate that the degree of deterioration observed under a definite set of test conditions is affected by the mechanics of the test set-up. This factor must not be ignored when one considers the commercial data presented by Mr. Halperin. I have not observed, however, that the differences in test set-up will alter the fundamental behavior involved, although they may affect the rate of deterioration. Thus despite wide differences in test set-up, the presence of moisture has always resulted in an acceleration of the mechanical deterioration in cellulose insulation.

It is true as stated by Mr. Halperin that the effects of oxidation do not disappear at temperatures above 120 degrees centigrade and I have tried to avoid any such impression. What I have tried to demonstrate is that, because of the importance of the purely thermal type of cellulose deterioration, chemical agents and mechanical means which might be effective in promoting the mechanical stability of cellulose at low temperatures where the oxidation effect is of importance must not be assumed to possess equal value in the stabilization of the cellulose at the higher temperatures obtained under overload conditions.

As indicated by Mr. Atkinson, the effect of moisture on insulation is of importance even when varnished materials are used. The relation between the chemical and mechanical changes in paper and the resulting power factor is a problem of commercial and technical importance.

I have followed the work of V. M. Montsinger in this field for many years. It is a pleasure to present data corroborating suggestions which he has made in the past and which have many times formed the basis for transformer design and operation.

I agree with Mr. Ford that other properties than tensile strength may be of value in the final analysis of those factors which affect the aging of cellulose. I find, however, that in a study of this type, limited objectives frequently result in faster progress than can be otherwise obtained. I hope that Mr. Ford or myself may sometime be able to present data covering the response of the compression and shearing properties of cellulose insulation to those factors which are discussed in this paper. With specific reference to the water content of the insulation when tested for tensile strength after aging, it has been our experience that the variation directly traceable to the difference in water content of the paper is of small magnitude in comparison to the total change described in the tests of this article. Attempts to follow a procedure such as suggested by Mr. Ford (extraction of oil and later humidification of the paper) have produced no worth-while results and frequently have raised questions directly related to the oil extraction effects. The work of Mr. Ford and his associates in this field has been of interest and value, and I hope that by the continued study of this problem in both of our laboratories we may contribute toward its ultimate evaluation and solution.

Application of Apparatus and Conductors Under Various Ambient-Temperature Conditions

Discussion and author's closure of paper 42-93 by R. E. Hellmund and P. H. McAuley, presented at the AIEE summer convention, Chicago, Ill., June 22–26, 1942, and published in AIEE TRANSACTIONS, 1942, August section, pages 553–8.

V. M. Montsinger (General Electric Company): This paper gives some very valuable information on ambient temperatures throughout the United States and how they should be used. I am particularly interested in the author's derivation of the equivalent ambient obtained when integrating the area by the eight-degree rule. This should be factored under certain conditions in the overloading of transformers in cool ambients. The American Standard Guides now permit one per cent overload for each degree that the daily air is below 30 degrees centigrade for self-cooled, and the daily water temperature is below 25 degrees centigrade for water-cooled transformers. The guides also state that the load should be decreased two per cent for each degree that the daily ambient exceeds these values. The question has been raised as to what should be

done in cases where the daily average ambient exceeds 30 degrees centigrade for a few days during the summer months. There are, no doubt, many days during the year in which the air is well below 30 degrees centigrade and where the one per cent overloading rule is not taken advantage of. In such cases it should not be necessary to derate the transformer during the few days when the average daily ambient exceeds 30 degrees centigrade.

The necessity for this derating can be overcome by increasing the ambient time period of 24 hours to one year. If the time period is increased to one year, the amount of overload should be based on the equivalent annual rather than the average annual ambient. The equivalent ambient is, of course, higher than the average ambient, since aging is not directly proportional to temperature. For example: by the eight-degree rule, six months' operation in a 30-degree-centigrade ambient and six months' operation in a ten-degree-centigrade ambient, is equivalent to 12 months' operation in 23.8 degrees centigrade or 3.8 degrees centigrade higher than the average value of 20 degree centigrade. Imposed on this, of course, is the difference between equivalent and average daily ambient, but this amount is small, being between 0.5 and 1.0 degree centigrade, and there is enough safety factor in the one per cent rule to take care of this difference. Hence, it is possible to use the daily *average* ambient instead of the equivalent daily ambient in applying the one per cent rule to daily overloads in cool ambients.

The use of the equivalent annual ambient will be advantageous in two ways.

1. It is a means—and apparently the only means—whereby the loading of transformers can be adjusted according to their annual ambient temperatures. In other words, transformers operating in the colder northern zone can be increased to give the same life as transformers operating in the warmer southern zone.

2. It will in many cases eliminate the necessity for derating during the few days in the summer months when the average daily ambient is above 30 degrees centigrade.

Whether the use of the average daily or equivalent annual ambient will permit the larger all-year output depends on local loading conditions. The conditions under which they should be used to determine the overload capability, are:

1. For one day emergency overloads, use the daily average ambient.

2. When the load is constant throughout the year, or when the greater capacity requirements are in the summer months, use the equivalent annual ambient.

3. When the greater capacity requirements are in the winter months, determine the equivalent ambient for the heavy-load months and for the light-load months, and check the load capability for both periods. This permits loading up to normal transformer temperatures in winter whenever the reduced summer load keeps the transformer temperatures to normal or lower on hot days.

The AIEE transformer subcommittee is studying the question of how to use annual equivalent ambients, and it is expected that its recommendations will be published in the near future.

P. H. McAuley: An error occurred in Figure 2 of the paper; curve 5 is for Helena and curve 6 for Bismarck.

Mr. Montsinger expresses agreement with the use of the equivalent annual temperature for determining apparatus loadings. In addition, he discusses operating conditions where it may be desirable to distinguish between daily and seasonal overloads. To obtain equivalent annual temperatures based on time-temperature curves as given for six cities in the paper is a rather laborious procedure and the essential data are not always available. C. F. Wagner has suggested an approximate method of determining the equivalent annual temperature. Only the average annual and monthly temperatures are used, such as given in the Atlas of American Agriculture, part II, section B, United States Department of Agriculture, 1928, for 626 cities. In this method aging units for each month at a given location are calculated with the eight-degree-centigrade rule and added to give annual aging units. A corresponding single temperature is found. From this calculated value the annual average temperature is subtracted. The difference is multiplied by 2 and added to the annual average temperature, which gives the equivalent ambient temperature. The factor 2 was obtained from a consideration of the equivalent temperatures for the six cities for which equivalent temperatures based on complete temperature-time curves are given in the paper. It is believed this method will give equivalent ambient temperatures in error not more than one degree centigrade. Because of the availability of the data required, this method has considerable merit.

Emergency Overloading of Air-Cooled Oil-Immersed Power Transformers by Hot-Spot Temperature

Discussion and author's closure of paper 42-115 by V. M. Montsinger and P. M. Ketchum, presented at the AIEE summer convention, Chicago, Ill., June 22–26, 1942, and published in AIEE TRANSACTIONS, 1942, pages 906–16.

Nicholas M. Oboukhoff (The Oklahoma Agricultural and Mechanical College, Stillwater, Okla.):

Part I

The following remarks primarily relate to transformers whose load is either residential or combined.

While industrial load can be characterized fairly by a single typical load curve, this can hardly be done in the case of the loads just mentioned above; the reason is that industrial load is relatively steady throughout the year, but residential and combined loads vary considerably, being correlated in some way with the seasons, specific months, and so forth. Dealing with industrial load one can be justified in using *daily* load factor derived from a typical curve instead of *annual* load factor; the difference will be small anyhow. Likewise, the period of 24 hours can be assumed as a basic one; operations like the integration of hot-spot temperature curves over this span of time, conclusions, and results referred to it are all in order and legitimate.

Yet with residential or combined loads a single typical load curve is a rather artificial construction; therefore, the proposal is that several ones should be constructed according to the seasons, specific months, geographical location, industrial development, and so forth, as a case may require, while the whole year should serve as a basic period of reference. A co-operation of the operators in furnishing necessary data would be needed and should be secured.

All this is yet to come. In the meantime, however, it is possible to see that the character of conclusions and recommendations already reached and offered by V. M. Montsinger and other research engineers and workers will hold substantially—with an enlargement and more boldness in the application of their methods to the residential or combined load transformers, as soon as the year has been adopted as the basic cycle.

Holding always in mind that the discussion is centered about those transformers, a general substantiation of the above view is as follows:

There is a considerable difference between the highest load peak and the lowest one in the course of one year. The load curves as

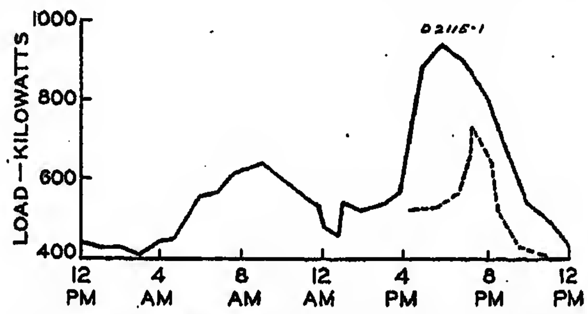

Figure 1. Residential and light industrial load curve

December 21, 1936
Maximum load 940 kw
Average load 595 kw
Ratio: average load to maximum 0.63
Ratio: rms current to maximum 0.65

shown in Figures 1 and 2 of this discussion have been obtained on a local system by me in 1936; new data have been added in 1938 which disclosed that the highest load peak occurred on November 6 and amounted to 2,180 kw averaged over a half-hour, while May 9 of the same year the load peak was as low as 1,400 kw, which makes 64 per cent of the highest one, the difference being 780 kw. This is not a local feature; for other sources[1] give the ratio of the summer load peak to that in wintertime as between 0.57 and 0.70 for the same kind of load curves. Annual load factor was 0.44—also in agreement with reference 1, while daily load factor amounted to 0.53 in November and 0.67 in May, weekly load factors being 0.53 and 0.62 respectively. Those highs and lows were not accidental; they belonged to the most loaded week in November and to the least loaded week in May respectively, while other peaks were close to those designated before, that is, 2,180 kw and 1,400 kw during these weeks, respectively.

Let us apply this situation to two cases: *First*, assume that a transformer is in a continuous operation throughout the whole year; then it would be only consistent to apply the three per cent[2] rule to the *annual*

load factor with the result that the permissible overload should be 16.8 per cent instead of 14.1 per cent during the high-load week and 11.4 per cent during the low-load one if the weekly load factors were used. The proposal is that the annual load factor be considered in determining overloads if transformers are continuously operated. As a matter of fact, the annual load factor is noticeably lower than the others for a residential or combined load; therefore, the suggestion is in the direction of a more liberal allowance.

Second, let us suppose that a bank of transformers is in operation, each transformer being uniformly loaded throughout the year; then a number of transformers simultaneously operated will be approximately proportional to a peak load with the result that it will depend on the seasonal or other variations of a load curve. In the given example approximately two thirds of transformers (exactly 64 per cent would be required to carry the peak for May 9, while full 100 per cent bank power would be used November 6; thus 780 kw would be in the reserve at the time it is needed the least. Because of the prominent normal peaks it is reasonable to expect overloading primarily during these peaks which at the same time, limit the duration of overloading; the latter would hardly last longer than the former; thus, the severity and duration of overloading are determined by the height of peaks and their duration in addition to other factors. The lower are the normal peaks, the milder and shorter will the overloading be.

An available reserve of power at the time of the *lower* peaks would be manifested by the fact that only a part—the major one though—of a whole set of transformers would be in operation, while the others are idle; it would result in the prolongation of their commercial—not technical—life; certainly this would be an advantage under normal circumstances.

It may be questioned whether or not this advantage would justify itself at the present time; one may argue, on the one hand, that what matters now is not a prolongation of the commercial life of a transformer but rather the harnessing of its power reserve for an actual operation *now;* one of the possible ways of doing this would be to allow

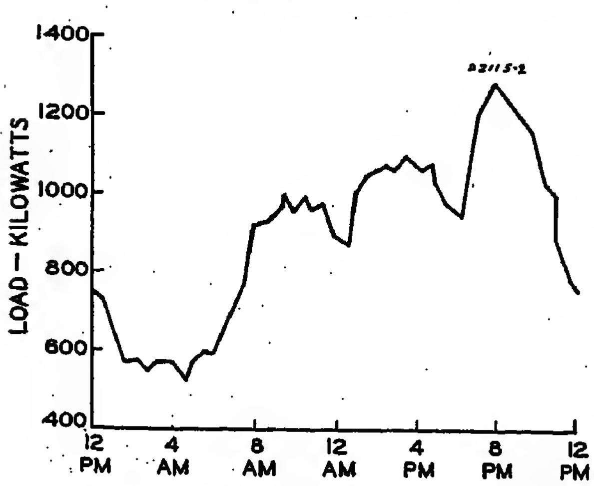

Figure 2. Residential and moderate industrial load curve

September 11, 1936
Average load 891 kw
Maximum load 1,275 kw
Ratio: average to maximum 0.70
Ratio: rms current to maximum 0.72

for such ultraoverloading at the time of the *higher* peaks that would limit or keep the commercial life from increasing, by affecting the technical life of a transformer involved; on the other hand, at the time when replacements might become difficult, a prolongation of the commercial life would be a valuable asset.

It goes without saying much that no finality is claimed as to specific values, examples, conclusions, and references given in the foregoing; they are offered to indicate general characteristics and trends and likewise call attention to a specific situation which is still fluid and not perfectly clear but already foreshadows the possibility of crystallization.

PART II

The implications of the discussed paper extend beyond the field of operation to that of design. Referring to the schedule of temperatures and Table VII, the discusser, for instance, reached the conclusion that standard design values of current density could be increased offhand by 18–27 per cent for transformers with 24-hour and 8-hour full industrial loads respectively. With standard design values of current density changed to higher values, cross-section areas of winding conductors will result in becoming smaller in inverse proportion, which means a considerable saving in copper; there will be more kilovolt-amperes per pound of copper or less copper per kilovolt-amperes.

The increased values of current densities thus revised are in agreement with the formula offered in my paper, "A Method of Successive Approximations in Electrical Design, Part II, Transformers," read before the Oklahoma Academy of Science at the annual meeting December 1937:

$$\Delta=\frac{622}{\alpha+0.035}\sqrt{\eta\frac{K_e}{K_s}} \qquad (1)$$

where

Δ stands for current density.
α stands for load factor.
η stands for core loss per pound.
K_e stands for price of winding conductors per pound.
K_s stands for price of steel laminations per pound.

As a companion formula the following one from the same paper is referred to:

$$A_s=C(\alpha+0.035)\sqrt{\frac{(\mathrm{KVA})}{4f}\,\frac{\Delta}{\eta B}}\times 10^3 \qquad (2)$$

where

A_s stands for net steel cross-section area of a core.
C stands for output constant.
(KVA) stands for output in kilovolt-amperes.
f stands for frequency.
B stands for flux density in the core.

2. EFFECT OF LOAD FACTOR ON OPERATION OF POWER TRANSFORMERS BY TEMPERATURE, V. M. Montsinger. AIEE TRANSACTIONS, volume 59, 1940, November section, page 636.

W. C. Smith (General Electric Company, San Francisco, Calif.): The problem of permissible overloads on transformers, as viewed by operators and maintenance men, has too often been beclouded by two misconceptions:

1. That the 105-degree-centigrade limit for the hot spot is a magical figure above which the transformer will burn up immediately and below which one can operate indefinitely.

2. That if by chance a transformer has been subjected to a high overload with no failure resulting, this is a proof that such overloads can be applied more or less indefinitely without damage to that unit.

We now know that a time-temperature relation exists as regards the deterioration of class-A insulation, its life being halved for every increase of from five to ten degrees centigrade operating temperature. At the point of "zero life" the insulation has lost its "water of constitution," still retaining however adequate dielectric strength, but is so brittle that a slight mechanical strain will crack it and lead to electrical breakdown. Many operators have experienced the fact that it is dangerous to move to a new location their old transformers or regulators which have withstood high operating temperatures for many years.

The hot-spot temperature is the weak link in the chain. Every reduction of a degree in temperature, whether secured by various methods of artificial cooling or by a lowering of the effective ambient insures longer life. Wartime demands for increased power, together with the scarcity of materials, are now prompting a careful review of all factors which can be utilized to allow higher transformer loadings with minimum consequent operating temperatures. To the writer it appears that two important possibilities have been quite neglected in any papers or discussions on this question, reference being made to the provision of sunshades together with the use of nonmetallic paint.

Ambient temperatures normally discussed are government shade readings, and it is important to realize that the effective ambient for transformers in the sunshine may easily be 5 to 15 degrees centigrade hotter. I recall measuring the oil temperature, at Redding, California, of an idle 25-kva lighting transformer out in the yard, during the middle of a day when the shade temperature was 114-degrees Fahrenheit (45.5 degrees centigrade). The oil was 136 degrees Fahrenheit (57.8 degrees centigrade). Here was a difference of 12.3 degrees centigrade due to absorption of the sun's rays. A suitable sunshade, presumably a semicircular louvered wood structure on the south side of a transformer bank, could therefore be counted upon to insure several degrees (centigrade) lower operating temperature during the hottest part of the day.

The use of cable leads to the transformer greatly facilitates the placing of the sunshade. In the case of vertical drop leads, it will often be necessary to rearrange them to a 45-degree angle to place the shade up over the transformer, insuring protection from the noonday sun.

In the western states, at least, the use of aluminum paint for outdoor transformers is

very widespread. A definite reduction in temperature rise should result from merely painting the north side of the tanks a dull black. A still further reduction will result if a sunshade is provided. Then it is very important to climinate all aluminum-painted surfaces, and for this dull black is also the best finish. A further advantage at this time of the dull black is to serve as a camouflage.

To summarize, it is believed that over and above the possibilities offered by special forms of artificial cooling, a marked improvement in the maximum operating temperatures of transformers may be secured as follows:

1. Paint the shady side of all outdoor transformers a dull black.

2. Provide a sunshade for protection during the middle of the day and then paint the entire tank with dull black. Provide a dull black paint on all indoor banks of transformers.

V. M. Montsinger: Mr. Oboukhoff's suggestion of using annual instead of daily load factor for use of the three per cent rule under certain load cycle conditions is somewhat outside the scope of the paper, although it does have a direct bearing on permissible overloads at a time when all the overload capacity that is available should be made use of. No work has been done to determine how much could be gained by using annual load factors instead of daily load factors; consequently it is not possible to give a figure at this time.

Mr. Smith brings up two very good points, namely, that of providing sunshades, and that of painting the side of the tank not exposed to the rays of the sun a dull black. There is no question but that a sunshade would effect a material reduction in the temperature of a transformer exposed to the sun's rays. The amount of temperature reduction will depend on the size and contour of the radiating surface. For a small distribution transformer with a plain tank, the reduction could easily be 10 to 15 degrees centigrade, whereas, for a large tank having attached radiators or cooling tubes, the gain would be less since a smaller percentage of the total developed surface would be exposed to the sun. My experience indicates that the reduction in temperature would be in the order of five to seven degrees centigrade for large power transformers. If one per cent load can be gained for each degree reduction in temperature, then the use of sunshades should enable users to gain from 5 to 15 per cent in capacity. In reality we should say that the use of sunshades should prevent the derating of 5 to 15 per cent, since the sun causes the temperature to exceed its normal temperature rise. However, there is for most outdoor installations sufficient breeze to counteract a large part of the increase in temperature caused by the sun's rays.

In connection with Mr. Smith's suggestion of painting the north side of a tank a dull black, the effect of this also will vary, depending on the size and shape of the cooling surface. While it is not possible to give any calculated values of reduced temperatures, some idea of the benefits can be gained by the following statements:

1. A plain tank, with a metallic finish, will give approximately 30 per cent higher temperature rise than one having a nonmetallic finish.

2. As the surface becomes more and more convoluted, the effect of the metallic finish on the temperature rise of transformer in the shade decreases, it being from five to seven per cent for the most complicated surfaces. In the sunshine there is essentially no difference whether a metallic or nonmetallic paint is used, although, as pointed out above, the temperature rise will be greater for either kind of finish. This question is discussed in the AIEE paper entitled "Effect of Color of Tank on the Temperature of Self-Cooled Transformers Under Service Conditions," by V. M. Montsinger and L. Wetherill.

A New Single-Phase-to-Ground Fault-Detecting Relay

Discussion and author's closure of paper 42-125 by W. K. Sonnemann, presented at the AIEE summer convention, Chicago, Ill., June 22–26, 1942, and published in AIEE TRANSACTIONS, 1942, September section, pages 677–80.

J. H. Neher (Philadelphia Electric Company, Philadelphia, Pa.): While Mr. Sonnemann is to be congratulated on the development of this relay which distinguishes between single-phase- and two-phase-to-ground faults, he is to be especially commended for pointing out before the Institute the possibility of using this or other equivalent devices in conjunction with a simple instantaneous ground relay to obtain high-speed differential bus protection on systems grounded through a relatively high impedance.

Although systems of bus differential protection employing special nonsaturating current transformers have been recently introduced, these systems are difficult to apply where the single-phase-to-ground fault current is appreciably limited. The arrangement proposed by Mr. Sonnemann not only facilitates the application of these systems in this case but also offers a means of obtaining high-speed bus protection against single-phase-to-ground faults with conventional current transformers.

While the possibility of obtaining a solid three-phase bus fault by the inadvertant closing of a switch without removing safety grounds is always present, nevertheless the use of a high-speed single-phase-to-ground fault system will initiate tripping on the majority of faults before the system is rendered inoperative by the spread of the fault to another phase.

L. F. Kennedy (General Electric Company, Schenectady, N. Y.): The author of this paper correctly points out the severity of the problem encountered when applying bus differential protection to installations where the ground current is small because of high neutral impedance.

Other methods also have been applied to obtain the desired operation under these limiting conditions. In two of these other solutions which have been used, one uses a relay to recognize the difference between the two-phase-to-ground and single-phase-to-ground faults, and the other uses a relay system which makes selective control unnecessary.

The first of these uses another and simpler means of distinguishing a fault which involves only one phase from one which involves two phases. This method likewise depends upon the circuit characteristics encountered when a neutral impedance or relatively high value is used. If we look at figure 6c in this paper we note that the zero-sequence voltage is approximately 120 volts peak for a single-phase-to-ground fault and approximately 60 volts peak for the two-phase-to-ground fault. Associated with these voltage conditions will be approximately a 2/1 ratio in the neutral current. Hence a simple current relay may be used which will operate for single-phase-to-ground faults and not operate for two-phase-to-ground faults. Applications of this type of relay have been used to supervise differential ground relays since 1939. While it can be shown theoretically that such a relay may fail to operate due to impedance in the fault, in practice the value of the neutral impedance is so high that it is difficult to consider this as a very real limitation, when used for bus protection.

The other method of solving the problem in the case of these high neutral impedance systems is to set up each phase separately in a differential system, using a total of only three relays, each one being sensitive enough to operate for ground faults as well as for phase faults. With transformers such as the air-gap core type or the linear coupler there may be a small differential current for through phase-to-phase-to-ground faults due only to manufacturing tolerances. Operation under this condition can be easily prevented by using only a small amount of "through" current restraint and one can still easily obtain adequate sensitivity to provide positive operation for internal single-phase-to-ground faults.

For this type of application the restraining feature just described is a generally applicable solution, regardless of system impedance variations, and therefore more desirable. It is also a method following established practice and with proved reliability and simplicity.

R. C. Ericson (Northern Indiana Public Service Company, Hammond, Ind.): This paper has been particularly interesting, since it has presented us with another tool for combating false residual currents.

It is felt, however, that the relay has a wider application than the author has inferred in the paper.

The requirement that the ratio of the zero-phase-sequence impedance to negative-phase-sequence be of the order of two to one seems a little too conservative. A ratio of 1.5 to 1 should probably be sufficient in most cases.

Another impression obtained from the paper is that the relay is not applicable to solidly grounded systems. It would appear that the question of applicability rests wholly on the apparent ratios of the zero- and negative-phase-sequence impedances, as

seen by the relay at the station in question.

The relay should also find some use in "direction comparison" pilot schemes (for instance, carrier-pilot relaying). This is particularly true of the schemes using the three-unit directional relay containing a voltage restraint unit and a polyphase and a residual power directional unit acting on one shaft. Schemes of this type very frequently employ a conventional residual current relay to remove the potential from the voltage restraint and polyphase power directional unit on the appearance of appreciable residual current. Experience has shown that under certain conditions this removal of potential is undesirable during two phase-to-ground faults.

A. R. van C. Warrington (General Electric Company, Philadelphia, Pa.): No relay session seems to be complete without a paper dealing with improvements in bus protection. For the past two years all efforts have been to improve current transformers. Now that saturation difficulties have been overcome by linear couplers and air-gap current transformers, the design engineers have again turned their attention to designing relays which will overcome the transformer errors still existing, in order to get still more sensitive bus protection.

The relay described by the author seems more complicated, however, than is necessary to do the job. A simple three-phase high-speed induction-cylinder undervoltage relay has been suggested, using two delta voltages and measuring the area of the station-bus delta-voltage triangle. The torque developed by this relay is proportional to the product of the two voltages and the sine of the angle between them. It can be shown that the area of the triangle during a single-phase-to-ground fault is essentially maintained during single-line-to-ground fault except with very low values of neutral impedance, while on phase faults or two-phase-to-ground fault the area will be drastically reduced, thus always assuring positive operation.

In the relay described in the paper the distinction between pickup on single-phase-to-ground faults and two-phase-to-ground faults disappears below a certain value of neutral impedance (R_n) which is one-third ohm in the example given. Below this value the relay torque reverses. Using the undervoltage relay scheme proper distinction is maintained even down to R_n equals zero. As a result it would appear that the three-phase undervoltage relay scheme using a simple high-speed induction-cylinder element is the simplest and most sensitive relay for this application.

W. K. Sonnemann: Mr. Neher's discussion goes one step beyond the points brought out in the paper and discusses the fact that a use of the new relay makes it possible to simplify the differential relays. The points made by Mr. Neher are well taken.

The author shows a ratio of 2/1 for a safety factor, but Mr. Ericson feels that a ratio of 1.5/1 would be sufficient in most cases. However, since the paper was presented, it has occurred to the author that, rather than apply the relay to the limits of some arbitrarily chosen safety factor, it would be better to determine the suitability of application by means of a few very simple calculations in the following manner: Consider an application in connection with bus differential protection. The relay should operate for a single-phase-to-ground fault on the bus. It should not operate for a two-phase-to-ground fault just outside the bus. Furthermore, it is possible that in some cases it should not operate for a two-phase-to-ground fault at the next outlying substation, depending upon the amount of current involved for the distant fault. It would therefore be in order to calculate the zero-sequence and negative-sequence voltages on the bus for the internal single-phase-to-ground fault and for the remote two-phase-to-ground fault as far removed from the bus under consideration as the application may require. Both of these calculations should include a reasonable value for possible fault impedance. Having obtained the voltage values for the two conditions, it is a simple matter to determine from the operating characteristic curve of the relay whether or not it is suitable. It may be that in some cases the curve shown by Figure 3 of the paper would not be suitable, but that some other curve for which the relay is capable of being adjusted would serve the purpose.

Mr. Kennedy mentions another method of discriminating between single-phase-to-ground and two-phase-to-ground faults by means of the relative magnitude of the zero-sequence current. This method is theoretically correct, but it is more than theoretically possible that such a relay may fail to operate because of impedance in the fault. The author knows of one case at least where the impedance of the fault was large enough to prevent the operation of such a relay.

The use of through current restraint has been and is quite practical and widely used. However, on multicircuit busses the complexity of using restraint certainly increases rapidly with the number of circuits. In view of this fact, the author feels that if the restraining coils of the differential relay could be eliminated by the installation of one additional relay as described in this paper, that the over-all installation would be simplified.

A. R. van C. Warrington mentions another method of using a relay responsive to the area of the station-bus delta-voltage triangle. This method has been considered by the author and his associates and considered to be more complex and difficult to predict than the method used in this paper. The area of the voltage triangle depends upon the negative- and positive-sequence voltages and the angle between them. The negative- and zero-sequence voltages at the bus are expressed as impedance drops from the source to the bus. If the positive- and negative-sequence voltages are used as Mr. Warrington would do, an additional factor is introduced: namely, the generated voltage. This enters in the positive-sequence network, and the determination of the relay characteristics is not as straightforward. It is difficult to understand Mr. Warrington's statement that the conventional relay and method he proposes appear to be simpler than the relay the author proposes. Actually, we feel that the reverse is true since no moving contact could be more simply actuated than by a spring supported armature without bearings. Furthermore, the sequence networks in the new relay are straightforward and of proved design.

In the oral discussion at the convention, the author pointed out that the relays could be utilized on systems where the grounding impedance is even less than the one-third ohm Mr. Warrington indicates in his last paragraph by the simple expedient of reversing the operating and restraining coils. However, we feel that this point is actually only of academic interest in that the need for the relay disappears on solidly grounded systems.

Protection of Pilot-Wire Circuits

Discussion and authors' closure of paper 42-136 by E. L. Harder and M. A. Bostwick, presented at the AIEE summer convention, Chicago, Ill., June 22–26, and published in AIEE TRANSACTIONS, 1942, September section, pages 645–52.

R. C. Ericson (Northern Indiana Public Service Company, Hammond, Ind.): The authors are deserving of some praise for their able presentation of the subject of pilot-wire protection. The material presented should prove of value not only to those engineers involved in designing pilot relay circuits, but also those working on communication, remote metering, or supervisory circuits.

W. R. Brownlee (The Commonwealth and Southern Corporation, Jackson, Mich.): The use of pilot-wire protection has made possible the successful design and operation of power-supply systems with significant savings in major equipment. The use of this valuable tool has not increased as rapidly as might be expected, and possibly the greatest retarding influence has been the feeling that sufficiently reliable pilot-wire circuits cannot be secured. Many years' experience with pilot-wire protection[1,2] (principally with leased circuit) have shown that an excellent degree of over-all performance of pilot-wire systems may be secured without requiring anything like 100 per cent continuity of the circuit, providing adequate continuous circuit supervision is included. However, the pilot-wire circuit must be protected from even momentary failures which by their very nature coincide with power-system trouble which may be on the circuit protected. There is still considerable confusion regarding the influence of power-system faults on pilot-wire circuits, and therefore the theoretical analysis of the authors is most timely.

What is believed to be the first installation in the United States of neutralizing transformers to protect pilot-wire circuits against rise of station ground potential was made in 1934 on the system of the former Tennessee Electric Power Company, and it was checked thoroughly by staged short-circuit tests in February 1935.[2] Many installations have since been made of three-winding neutralizing transformers to protect against rise of station ground potential, and for that purpose, these appear to have some important advantages over the two-

winding capacitor excited transformers now offered.

1. The three-winding unit provides genuine "neutralization" (see Figure 9 of paper) of the voltage rise so that terminal equipment and pilot-wire cable are unstressed, whereas the two-winding device acts as a voltage divider, resulting (Figure 9c) in impressing some 1,000 volts on the pilot-wire cable insulation for a total rise of only 2,000 volts. Protective devices connected between the conductors of communication-type cable and the sheath will operate to short-circuit and ground the pilot wires at such voltages. It is doubtful if this difficulty can be overcome by the addition of capacitors without introducing other complications.

2. If connected as shown in Figure 6 of the paper, the magnetizing capacitors become equivalent to 0.5 microfarad connected across the circuit at each terminal. With even reasonably short pilot-wire circuits, the cable capacitance will be of the same order, so that the total will be beyond the maximum recommended for use with certain two-wire differential-type pilot-wire schemes.

3. It is possible that the two-winding transformers and capacitors are subject to transient effects such as were encountered with an early design of transformer which was built to neutralize induced voltages.[3] Actual fault tests on this unit showed an initial unneutralized voltage for the first cycle which was nearly as great as the total unneutralized voltage. Thorough short-circuit tests should provide a definite answer, and, if these had been made, the results should be of interest.

The authors' statement that no specific protective measures are required in many cases is true but should be used with considerable caution. For example, it is sometimes thought that the connecting of the power-station ground networks and the communication-system protective grounds to the same water system obviates the need of protection. Short-circuit tests have disclosed as much as a 2,000-volt drop between the water service connection at a power station and remote ground caused largely by the impedance of the meter and service connection.

The authors mentioned an effective primary impedance of a three-winding neutralizing transformer as some 11,000 ohms compared with 100,000 ohms for the two-winding transformer. Several installations have been madeof three-winding neutralizing transformers with a primary impedance exceeding 100,000 ohms at 4,000 volts, 60 cycles.

Is circuit neutralization achieved by the connections of the two-winding transformer shown in Figure 6, or must the insulating transformer of Figure 8 be used? If Figure 6 is adequate, then the need for the insulating transformer of Figure 8 is questionable.

3. NEUTRALIZING TRANSFORMERS. Edison Electric Institute publication H-12.

K. H. Perkins (Bell Telephone Laboratories, Inc., New York, N. Y.): Neutralizing transformers to prevent extraneous low-frequency longitudinal voltages from appearing on communication or signaling circuits have been in use for a long time and have formed the subject of a number of papers before this Institute. The device which the authors refer to as a two-winding neutralizing transformer might more properly be called a new name for an old tool: namely, the longitudinal choke, under which humble label it has been known for a long time. To regard this choke as a neutralizing transformer may possess advantages when comparing this device with the conventional type of transformer. The most interesting and valuable parts of the paper are the sections devoted to methods for computing the distribution of voltage along the protected conductors.

It should be pointed out that pilot wires are frequently in a cable containing other communication or signaling circuits. The type of service on these accompanying circuits may be such that momentary interruptions, such as might be occasioned by the operation of lightning arresters or protectors during fault conditions on the power system, are not serious. However, it is necessary under these conditions to make certain that the insulation between the pilot-wire pairs and the other conductors is not stressed dangerously, because breakdown of this insulation might result in failure of the pilot-wire circuits. It may therefore be necessary in a situation of this kind to provide all of the circuits with the same kind of protection as the pilot-wire circuit. Many different situations, in which this question of potentials between conductors is involved, may be encountered in practice, and each situation must be worked out individually. It is intended here merely to point out that in order to protect the pilot-wire circuits themselves, attention may have to be given to other circuits in the cable besides the pilot-wire conductors.

In the section dealing with the three-winding transformer, it is implied that the potential of remote earth is reached a few hundred feet from the station ground. While it is true that in most cases the largest part of the potential between the station ground and remote ground takes place within a few hundred feet, frequent cases have been encountered in which it was advisable to carry the primary connection out to as much as several thousand feet. In commercial telephone circuits, the remote ground must be located far enough from the station ground so that the remanent voltage will not cause operation of protector blocks. Local conditions determine the potential distribution, and it is advisable to fix the position of the primary ground by test.

In the discussion of the two-winding transformer, it is stated that the latter is more effective than the three-winding transformer, because neutralization is aided by the exciting current in the case of the two-winding transformer and hindered by it in the case of the three-winding transformer. This comparison has no very great significance, because many other factors enter into the relative merits of the two types of transformer, and by proper design either can be made as effective as desired. By admitting the exciting current to the signal circuit itself, rather severe balance requirements are placed on the longitudinal circuit and upon the grounding capacitors. Otherwise, the flow of longitudinal current may give rise to metallic voltages which might interfere with the relay operation. Also, since capacitors are used to provide a path to ground for the exciting current, the device is restricted to circuits using d-c or low-frequency signals.

In the discussion of potential distribution resulting from combined station-ground potential rise and magnetic induction, it is stated rather positively that the voltages produced by these two effects are 90 degrees out of phase. It should be recognized that this is only an approximation. Actually, the phase angle between these voltages depends upon the earth resistivity and the separation between the power circuit and the signaling circuit. For example, at a separation of 200 feet and an earth resistivity of 100 meter-ohms, the phase angle is about 65 degrees.

L. L. Fountain (Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa.): This paper gives information for which there has been a definite need for some time. This need has been intensified by the rapidly increasing use of the pilot-wire relay. The information given in the paper should serve to prevent the recurrence of difficulties which have been encountered heretofore caused by a lack of understanding of the pilot-wire requirements with respect to induced voltages and station ground potentials. Investigation has shown that, in practically every case, proper pilot-wire protection results in satisfactory relay operation.

In the closing paragraph of the paper, reference is made to leased pilot wires. While there is probably no place in the paper for further amplification of this subject, there is a definite need for more information on the characteristics of the available pilot-wire circuits that can be leased and the conditions under which they may be made available.

The authors make mention of the fact that "the seal-off voltage of the arresters must be above the maximum voltage that can be impressed on them by induction in the pilot wires, and so forth." This point deserves special emphasis. Since leased circuits have a fixed insulation level and utilize carbon protector blocks (arresters) to suitably protect the cable insulation, little variation is possible in these facilities. It is, therefore, essential to determine that the longitudinal induced voltage to which the pilot-wire pairs may be subjected is below the breakdown value of the carbon blocks in order to determine whether or not the circuit is suitable for use with pilot-wire relays. In the past, a few isolated cases of trouble have occurred because of the failure to observe this precaution; however, it is believed that continued co-operation between the telephone company, utilities, and electrical manufacturers will result in a better understanding of the conditions and prevent the recurrence of this phenomenon.

The method of presenting this difficult subject has been admirably handled, and the authors should be commended for their effort.

E. L. Harder and **M. A. Bostwick**: Before commenting on any of the discussion, the authors wish to express their appreciation of the interest shown in this paper. It was prepared to review the problem of protecting pilot-wire circuits, calling attention to methods that can be used to determine the distribution of voltage stresses that are

imposed on those circuits, and to present a new type of neutralizing transformer that is of value for protection of these circuits. The discussion of the relative merits of different types of neutralizing transformers was merely incidental, since the primary object of the paper was to call attention to the problem of protecting pilot-wire circuits. Once that problem is appreciated, it is assumed that inherent difficulties, that may have been previously overlooked, will be avoided.

In reply to Mr. Brownlee's discussion we agree that each type of neutralizing transformer, three-winding or two-winding, has certain advantages over the other. As pointed out in the paper, however, it will be noted that the two-winding neutralizing transformer is particularly well adapted to the protection of pilot-wire circuits, which are subject to both induction and differences in ground potential. The "voltage-divider action," cited under the first paragraph of Mr. Brownlee's discussion, and illustrated in Figure 9c of the paper, is only incidental and was illustrated in the paper to guide users so as to avoid the condition. Figure 9b illustrates the correct use of the two-winding neutralizing transformer. The required capacity between the pilot-wire circuit and ground may be provided either in the form of the natural capacity of the circuit or by adding lumped capacity. In either case the required capacity is well within the operating range of a-c pilot-wire relays that are now on the market.

Figure 6 of the paper was used to illustrate schematically the proposed relay circuit. Actually this circuit is made up as shown in Figure 4. Since the 0.5-microfarad capacitors are connected between mid taps of the insulating transformer and ground, it will be noted that this capacity is not introduced into the relay circuit. Consequently, the operating limits of the associated pilot-wire relay are not affected by this connection.

The circuit tests that are suggested in Mr. Brownlee's third paragraph have been in effect performed by several years experience in operating pilot-wire circuits identical with those described in this paper. A consideration of the circuit will reveal that the transient effects questioned are only of interest when they are introduced into the pilot-wire loop. Normal action of the two-winding neutralizing transformer is to introduce a high impedance into the series circuit that is made up by paralleling both pilot wires and connecting them to ground through the terminating capacitors. Since this circuit must be symmetrical—that is, equal impedances are introduced into both pilot wires—, it will be noted that any transient disturbance set up by transmission-line faults will not introduce extraneous voltages in the pilot-loop circuit. Consequently, the effect which Mr. Brownlee has feared, is not encountered. This is borne out by actual operating experience.

Adequate neutralization of all voltages, within the operating range of the two-winding neutralizing transformer is obtained by use of the circuit which is schematically illustrated in Figure 6. The insulating transformer shown in Figure 8 is not required, as the residual voltage on the relay side of the neutralizing transformer is in the order of 1.3 per cent of the applied voltage. However, the circuit illustrated requires the ratio change and mid tap connection that is provided by the insulating transformer shown in the diagram. Since this is standard apparatus, the insulating transformer is used rather than supplying an additional device.

We agree with Mr. Perkins' statement that the two-winding neutralizing transformer has been previously used as a "longitudinal choke." While these two pieces of apparatus are of similar construction, the actual design and use differ quite radically. The device which we have described is of particular value for protection of pilot-wire circuits, while the "longitudinal choke coil" was designed especially for communication circuits.

We appreciate having Mr. Perkins call our attention to the fact that voltages between wires in a given cable must be considered. This is most important, and the problem must be studied to avoid the possibility of transferring voltage stress from one circuit to another within a given cable. As pointed out in a paragraph that was added to the paper for publication in AIEE Transactions, "generally, all wires entering a cable at a given point should be protected in a similar manner." We also agree with Mr. Perkins' statement that it is advisable to fix the position of the primary ground by test rather than relying upon the assumption that average earth potential will be found a few hundred feet removed from station ground. The fact that the station ground potential may be less than 90 degrees out of phase with the longitudinally induced voltage was neglected, as a quadrature addition of these voltages is sufficiently accurate for the purpose of this discussion.

As both Mr. Perkins and Mr. Brownlee have pointed out, the design details of the different types of neutralizing transformers discussed in the paper are not fixed. The impedance of either design may be changed to suit the particular application. For example, the shunting action of the exciting capacitors, used with the two-winding neutralizing transformer can be reduced by grounding these capacitors through a mid tapped reactor. The impedance of this reactor can be chosen so as to avoid shunting high-frequency currents out of the pilot circuit and yet to shunt low-frequency currents, such as third harmonic currents, if this is considered desirable.

Current- and Potential-Transformer Standardization

Discussion and author's closure of paper 42-116 by the AIEE current transformer subcommittee of the committee on protective devices presented at the AIEE summer convention, Chicago, Ill., June 22–26, 1942, and published in AIEE TRANSACTIONS, 1942, September section, pages 698–706.

L. F. Kennedy (General Electric Company, Schenectady, N. Y.): The interest of the relay engineer in these standards will be largely concerned with the sections covering the specification of accuracy classes for relaying service and the application data to be made available.

In connection with the method of specifying overcurrent performance for example $10L400$ or $2.5H200$ it should be remembered that this subject has been under active consideration for many years. During this time many suggestions have been made as to how this specification could be given in such a way as to convey the maximum information. From these several suggestions either or both of two points always seemed to be significant. One was the realization that current-transformer errors increase rapidly after reaching the ten per cent value. The other was the desire to know the performance at 20 times current. Your working committee has succeeded in combining these two ideas in a specification which tells the voltage (or burden) permissible without exceeding a ten per cent error at 20 times secondary current. For those who prefer a burden figure to a voltage figure, it may be in order to emphasize that the last number in the accuracy specification divided by 100 gives the permissible burden in ohms.

Incidentally, I believe the committee should be congratulated for finally establishing ohms as the basis of expressing burden in preference to the volt-ampere expression which was almost meaningless for relay work where operating values other than five amperes are so frequent.

The section on application data recognizes the usefulness of the excitation characteristics as a means whereby the actual error under specific conditions may be accurately determined. It would appear that the best method of presenting and using these data has not been established. Three methods of calculation are indicated in Appendix 2, and figure 5 shows a graphical solution. The text indicates that the published information should include excitation current versus voltage and "sufficient data to determine" inphase and out-of-phase current, or phase angle. Since all of the indicated methods use either φ, directly or the components of I_e which are obtained by knowing φ_e, it would seem to be in order for the committee to definitely recommend that the angle of the exciting current together with the magnitude constitute the basic data.

E. C. Eberhardt (Commonwealth and Southern Corporation, Jackson, Mich.): The paper should be very helpful in giving a better understanding of section 4 of the revised American Standard for Transformer, *C*-57 when it is published. The latter part of the paper obviously reproduces certain parts of section 4 as now revised, although it is not clearly identified as such in the paper. Including this material for reference permits a better understanding of the discussion in the paper and also makes this information generally available in advance of the publication of *C*-57 which should be helpful to those interested in this equipment.

"Standard Accuracy Classes for Current Transformers for Relaying Service"

The paper clearly states the purpose of these accuracy classes for relaying service; namely, they provide a bench mark for comparison and for specifying the overcurrent accuracy requirements and establish in a general way the limits within which a given

transformer does not exceed specified errors. That is, the method of classifying the accuracy is standardized, but no recommended or preferred classifications for standard production units have been indicated either by this paper or in that part of section 4 reproduced in the paper. The considerable number of accuracy classifications in the standard are required in order to provide the necessary "bench marks" for standard production units and for special requirements. Another important function of standardization might readily be accomplished by establishing specific accuracy classes as standard or recommended for certain general applications in which current transformers are widely used. Thus wound-type current transformers suitable for applications such as the general requirements of electric-power stations, both for metering and general relaying, might for example have a recommended accuracy classification of 3/10 *B*1/10, 3/10 *B*5/10, 3/10 *B*2; 10*H*100, 2.5*H*100. Such emphasis on specific classifications should serve as an incentive toward standardization in specifying accuracy requirements and for uniformity in standard catalogued transformers.

Under 4.032 (*a*) (2) of the proposed revison of *C*-57 it is specified that a current transformer shall be given an accuracy rating in accordance with the maximum secondary terminal voltage at which the specified error will not be exceeded under the conditions specified for rating purposes. Apparently the intent of this requirement is to insure that the accuracy rating shall be a true bench mark of the unit's ability. That is, where a standard available design having an accuracy rating of 10*H*100 is furnished to meet a specified accuracy class of 10*H*50, it shall be given its rating of 10*H*100 and not the lower rating, which could happen under the maximum error-limit requirement only. It is commendable that this provision has definitely been included in the standard so as to avoid possible confusion and misunderstandings.

Mechanical Limit for Current Transformers

The paper provides an interesting discussion on the revised method of expressing the mechanical limit of current transformers and also indicates test conditions by means of which the completely offset requirement may be demonstrated. Since the stated tests are equivalent to the completely offset condition being maintained for six cycles and also definitely establish a crest value of not less than 2.82 times the rated mechanical limit expressed in symmetrical rms amperes, they represent the extreme in completely offset requirements and hence should demonstrate the unit's ability without question. However, the standard does not specify this demonstration, and the paper merely reads "may be demonstrated." Unless the above demonstration or some other common basis is definitely recognized, so that the mechanical limit rating indicates a definite ability, the present confusion as to what is meant by the claimed ability will continue to exist.

The proposed standard specifies that the symmetrical rms mechanical limit rating shall not exceed one-half the thermal limit of six cycles. Such a requirement would be necessary to provide adequate thermal ability for a demonstration test such as that indicated in the paper.

110-Kv Insulation Level

Tables IX and X of the revised standard make the new 110-kv basic insulation level applicable to instrument transformers in insulation class 15*H*. This should permit appreciable savings where instrument transformers are desired having an impulse rating comparable to the power level in the 15-kv insulation class. Formerly, it was necessary to go the 150-kv impulse-rated units or purchase special nonstandard units. It is interesting to note a definite trend in catalogued equipment toward adoption of the 110-kv impulse rating instead of the 95-kv level for 15-kv outdoor units of certain types.

F. E. Davis (The Commonwealth and Southern Corporation, Jackson, Mich.): It seems to me that metermen, in general, should be most interested in and pleased with the fact that we now have a standard method for rating instrument transformers that is of greater significance from a metering standpoint than the method formerly used. Formerly, only arbitrary limits for ratio error and phase angle of the transformers were used for rating purposes. Now, arbitrary limits for the effect of the transformer ratio error and phase angle on the accuracy of measurement are used, and this is the factor with which metermen are primarily concerned. Thus, the ratings given transformers on the new basis define closely the limits of the extent to which the transformer characteristics affect metering accuracy.

I might also call attention to the fact that, in rating current transformers for relaying service by the new method, it is necessary to rate them both under the 2.5 per cent and 10 per cent specification (such as 2.5 *H* 50 and 10 *H* 200). This is for the reason that a rating under one condition is not indicative of the performance under the other in all cases. (For instance, a 2.5 *H* 200 rated transformer would also meet the 10 *H* 200 requirement, but the reverse is not necessarily true. Both, therefore, should be specified.)

S. D. Moreton (General Electric Company, Philadelphia, Pa.): The proposed American Standard for Current Transformers requires that the manufacturers now give the excitation characteristics of the transformer. This makes it possible for the customer to calculate the transformer errors for his particular application resulting in better system co-ordination than was possible heretofore when interpolation between the standard ratio curves was the only method available aside from actual test.

The authors of this paper have mentioned several methods for the calculation of ratio correction factor and phase-angle errors of current transformers. I wish to stress that any mathematical method will be long and tedious unless one is willing to accept the inaccuracies of adding the magnitude of the exciting ampere-turns arithmetically to the secondary ampere-turns to obtain the primary ampere-turns. The chart method as mentioned in appendix 2 under "Method 2" as shown in figure 5 of the paper is in reality a vector method for the addition of the exciting ampere-turns and the secondary ampere-turns to obtain the ratio correction factor and phase-angle (β) directly. This vector method is the ideal answer for rapid and accurate calculations: by the use of vector charts of this nature calculations may be made in one-fifth of the time required for mathematical analysis, with an accuracy that is far superior to slide-rule work.

An example would perhaps show more fully the labor that is avoided by use of the chart method. Let us assume that the value of the exciting current has been determined from the burden requirements:

as $\bar{I}e = 5\sqrt{60} = 2.5 - j4.33$
where $\bar{I}s = 25\sqrt{30} = 21.65 - j12.5$

The following steps must be performed if method 1 in Appendix 2 is used:

$$I_p = \sqrt{(21.65+2.5)^2+(12.5+4.33)^2}$$
$$= \sqrt{(24.15)^2+(16.83)^2} = \sqrt{583+284}$$
$$= \sqrt{867} = 29.4 \quad \text{amperes}$$

RCF = 29.4/25 = 1.175

$$\beta = (\tan^{-1} 16.83/24.15) - 30 \text{ degrees}$$
$$= (\tan^{-1} 0.698) - 30 \text{ degrees}$$
$$= 34.9 \text{ degrees} - 30 \text{ degrees} = 4.9 \text{ degrees}$$

The mathematical addition of two vectors requires that squares and square roots be taken as well as the use of trigonometric functions in relatively complicated formulas as indicated by the authors' methods; these calculations are especially laborsome if numerous points are required as for curve drawing.

The steps involved in performing the calculations by the use of vector charts are

Per unit exciting current $= \bar{I}e/\bar{I}s$
$= 5\sqrt{60}/25\sqrt{30} = 0.2\sqrt{30}$

Using the chart given in figure 5 of the paper the ratio correction factor and the phase-angle error (β) are determined directly as:

RCF = 1.177
$\beta = 4.85$ degrees

By the use of the vector-chart method 80 per cent of the time can be saved, greater accuracy obtained, and the calculations readily made. Thus a simple and rapid means for calculation, that does not lose any accuracy through the process used to obtain the result, is the one that should become the predominant method—the vector-chart method.

C. A. Woods, Jr. (Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa.): 1. This report covering the recent work of the current transformer subcommittee gives some insight into the vast amount of work involved in obtaining a set of standards which meet present-day requirements without any material conflict with past practices. The discussions and explanations on the revisions and new ma-

terial of these standards gives the user of this apparatus a better picture of the characteristics and limitations of instrument transformers.

2. The new sections covering current-transformer accuracies and application data are of particular interest to the application engineer. The use of the saturation or excitation curve made from data measured on the current-transformer secondary winding with the primary winding open-circuited for determining performance is emphasized. It might have been well to point out, that when a satisfactory method of determining and expressing the secondary leakage reactance of current transformers has been accepted, the standards could dispense with the use of ratio and phase-angle errors as a means of accuracy classification of overcurrent performance. Then, excitation characteristics could be used exclusively.

3. Appendix 2 gives 3 methods of calculating ratio correction factor and phase angle from the magnetizing and loss characteristics. As stated, all three methods are simply different means of obtaining the solution of the vector diagram Figure 3. Method 1 is the fundamental solution and most readily followed. Method 2 has its principal interest in its accompanying chart, Figure 5. Amplification of the use and limitations of this chart would be of interest. Method 3 is another form of the expressions given in method 2. It would seem method 1 is so simple and fundamental that it would be the desired method, eliminating the inconvenience of requiring special charts or formulas to be always available. Likewise, it is a constant reminder that the ratio of the excitation current, I_e, to the load current, I_s, is all that is required for a large percentage of applications.

4. It is felt this report will stimulate the use of the new standards and further investigation of transformer performance.

J. E. Clem (chairman of committee): The members of the committee are gratified that the discussions have been so complimentary and so constructive.

Mr. Moreton expresses a strong preference for the chart method of determining the performance of current transformers in the overcurrent field, while Mr. Woods expresses a strong preference for method 1. It is hoped that those who use any of the methods given for calculating overcurrent performance will compare the various methods carefully and express an opinion so that the committee may recommend a preferred method for inclusion in *C*-57 as an addition to the test code.

Likewise Mr. Kennedy's suggestion that the exciting current data required be on the basis of magnitude and phase angle is also a matter on which an expression of preference is desirable.

Mr. Eberhardt suggests that specific accuracy classes be established as standard or recommended for certain applications. Such material does not belong in a standard of this nature. Such information might take the form of an industry report and, if a nearly unanimous opinion could be obtained, included as an appendix to the standard under the heading "Guides for Application."

Mr. Eberhardt notes that the standard does not require that the mechanical limit of current transformers be demonstrated. Actually the standard does not require that any of the characteristics be demonstrated, either in section 4 or in the other sections of *C*-57. The standard requires that the apparatus have certain characteristics, and whether or not tests are made to demonstrate that the apparatus fulfills the requirements is a matter of manufacturing practice and expression of customer's wishes.

Mr. Davis suggests that current transformers be given an overcurrent rating at the 2.5 per cent point as well as the ten per cent point. This is not practical, because the second point would not really be indicative of the performance of the transformer. Because of the fact that the voltage steps are multiples of 2, starting with 50, the voltage corresponding to 2.5 per cent would be between the standard voltage values, and any rating for the 2.5 per cent accuracy would therefore be misleading.

Study of Driven Rods and Counterpoise Wires in High-Resistance Soil on Consumers Power Company 140-Kv System

Discussion and authors' closure of paper 42-107 by J. G. Hemstreet, W. W. Lewis, and C. M. Foust, presented at the AIEE summer convention, Chicago, Ill., June 22–26, 1942, and published in AIEE TRANSACTIONS, 1942, September section, pages 628–34.

J. R. Eaton (Naval Training School, Purdue University, Lafayette, Ind.): The studies described in this paper show that if lightning strikes a tower equipped with both buried counterpoise wires and deep-driven ground rods, the resulting current in the ground rods is much greater than the current in the counterpoise wires. From this behavior, it is logically concluded that the deep-driven rods provide a more effective ground than do the counterpoise wires.

In comparing the merits of the driven ground rod and the counterpoise wire in the light of the performance observed in Michigan, it may be well to call particular attention to one peculiarity in the geology of the region in which the studies were made. As implied by conclusion 2, the high-resistance sandy soil of this region is underlaid by a different kind of soil (presumably clay) which is of relatively low resistivity. Rods driven deep into the sandy layer provide a relatively high-resistance ground connection. When such rods are driven sufficiently deep that the underlying clay layer is penetrated, the resistance drops rapidly, indicating that by far the greater part of the conductance is through the clay soil. The superior performance of the deep-driven ground rods as observed in the Michigan tests is very likely principally because of the fact that the rods make contact with the highly conducting soil layers considerably beneath the surface.

It must not be concluded from these tests that deep-driven rods will in every case be superior to horizontal buried wires. Only in case the deep rods penetrate lower-resistance soil layers below the surface, can the rods with certainty be considered as superior to the buried counterpoise wires.

S. K. Waldorf (Pennsylvania Water and Power Company, Baltimore, Md.): Hemstreet, Lewis, and Foust have evaluated the relative merits of rods and counterpoise as collectors of lightning current. What must of necessity be of prime importance to transmission engineers is the relative effectiveness of these two types of auxiliary grounding in the prevention of flashovers. It will perhaps help answer this question if the authors in their tabulations of footing resistances and tower currents would indicate which were associated with relay operation and where evidence of flashover was found. In other words, do the data give any indication that rods or counterpoise are the more effective in the prevention of flashovers?

Hamilton Treadway (United States Department of Agriculture, St. Louis, Mo.): The authors have conducted a most interesting and enlightening study of the characteristics of grounding methods under actual field conditions. This paper is a most valuable contribution to the literature on this subject.

A point of interest on which the data do not shed light is the time-impedance characteristic of the ground electrodes during the lightning stroke. The methods of measurement of course did not lend themselves to obtaining such characteristics. However, the existence of a high initial impulse impedance has been a point of some controversy although established by theoretical analysis. It is unfortunate that the data presented do not enlighten us on this point. It is, of course, needless to point out that the existence of an initial impulse impedance in excess of the Megger values would result in some instances in potentials much greater than the flashover characteristics of the line. Of course, such voltages would exist only for a few tenths of a microsecond. The opinions of the authors on this point are desired.

The very low ratios of surge impedance to "normal impedance" is to be expected in high-resistance soils. As has been previously suggested either the counterpoise or driven ground rod is essentially an imperfect capacitor in series with a resistance and inductive reactance. The contact resistance between the soil and the grounding electrode is paralleled by the capacitance of the rod. During the surge the contact resistance is effectively shunted out. Therefore, where higher "normal" impedances are indicative of high-contact resistances accompanied by large rod capacitance, the ratio of impulse impedance to the "normal" impedance will be quite low. This, of course, means that the true criterion of the effectiveness of the ground is the leakage resistance. In other words, the "normal" or d-c or 60-cycle impedance measurements are of value only insofar as they indicate the magnitude of the leakage resistance. It is probably true generally that low "normal" impedances indicate low-contact resistances and high "normal" impedances indicate high-

contact resistances. This is probably also true of the leakage resistance.

It is believed that leakage resistances will be reduced most effectively by deep grounding. This is indicated by the data presented and the conclusions of the authors.

J. H. Hagenguth (General Electric Company, Pittsfield, Mass.): This paper is of considerable interest because it gives results of lightning strokes to lines with unusual grounding conditions. The knowledge gained by this and similar investigations has helped considerably to improve the lightning performance of transmission lines. I believe that considerably more information can be obtained from the data than has been given in the paper.

The records obtained indicate for lines equipped with ground wires:

(*a*). The current waves in the stricken tower have relatively steep wave fronts and relatively short tails.

(*b*). Due to the steepness of the wave front, the ground impedance of driven rods and counterpoise wires is considerably higher than low-frequency resistance measurements indicate at the stricken tower.

(*c*). Measurements of crest currents in ground wires and towers can be used to calculate the approximate wave shapes in the stroke, in the towers, and in the ground wires.

These points are shown in somewhat more detail, from the results presented, as follows:

1. At towers close to the point of contact of the lightning stroke, the driven rod conducts currents of the order of three times as great as conducted by a counterpoise indicating that the impedance of (2) counterpoise wires in parallel is of the order of four times as great as that of a driven rod. (The ratio of currents in the driven rods to the currents in the counterpoise are: Table VIII, *T*-7,708—5.37; Table X, *T*-7,715—2.75; Table XIV, *T*-7,721—3.00.)

2. At towers a few spans distant from the stroke, the counterpoise may conduct as much or even more current than the driven rod (as shown in Tables VIII, towers 7,705 and 7,711; Table X, towers 7,712, 7,716, to 7,723 inclusive). As shown under paragraph 5 of this discussion, the current fronts are slow at such towers and therefore counterpoise resistance may be equal to or less than the resistance measured with low frequency. Since the counterpoise is installed at the top of a very thick layer of sand, seasonal or even day by day variations in counterpoise resistance should be great depending on the moisture content of the sand. The driven rod reaching below the sand layer should be affected to a much lesser degree. This seems to be indicated by stroke 6, Table XIV, where at towers, 7,716 to 7,719 and 7,722, 7,723, in spite of high driven rod currents, no counterpoise currents were measured.

3. At the stricken tower where the ground impedance is effective rather than ground resistance, seasonal variations are small (see paragraph 1).

4. The effective impedance of the grounding system at the stricken tower is several times the resistance measured by low-frequency means (d-c or a-c). Stroke 6, near *T*-7,721, Table XIV, caused flashover of three insulator strings at *T*-7,721, (1.5×40 negative flashover voltage of 760 kv), although the product *IR* (neglecting counterpoise resistance) was 10 ohms × 56,000 amperes which equals only 560 kv. Actually, the flashover voltage will be considerably greater on account of the coupling factor between line wires and ground wires and the short time during which the high voltage is applied as will be shown later. The actual flashover voltage, taking into account these factors, is of the order of 1,200 kv. The effective impedance for the stroke at tower 7,721 is therefore $\frac{1,200,000}{56,000}=21.4$ ohms. The ratio of counterpoise impedance to driven-rod impedance equals three on the basis of the inverse ratio of their currents. Further, the two counterpoises and the driven rod represent a parallel connection of impedances. From these two relations between the impedances, the ground-rod impedance at current crest calculates as 28.5 ohms or 2.85 times the low-frequency resistance, while the two counterpoises have a combined resistance of 85 ohms or 170 ohms each. Such high values of counterpoise impedance have been shown to exist from tests[1,2] on counterpoises and are due to steep front current waves.

5. From the data showing currents in the different grounding structures caused by the different strokes, a fair estimate of the wave shapes involved at the different towers can be made, using traveling wave theory. However, instead of repeated reflections, use is made of the fact that a transmission line after a few reflections changes from a surge impedance into an inductance. A simplified circuit such as shown in Figure 1 of this discussion results, and this can be solved with second power equations. Further, instead of voltage waves, a current wave of a desired shape is injected into the circuit representing the stroke current. This obviates the use of the unknown surge-impedance value of the lightning stroke. The resulting current waves in ground wires and towers in a section typifying towers, 7,713, 7,714, 7,715, 7,716, and 7,717, stroke 3, Table X are also shown on Figure 1, assuming a wave shape of the lightning stroke as 2×40 and equal ground resistances at all towers, as well as equal inductance per span as shown on Figure 1. This figure does not use actual resistances but shows the mechanism involved at the ground end of a lightning stroke to a ground wire.

6. It is impossible here to go into any detail about the accuracy of the method. However, Table I shows a very good check between calculations and measurements for towers 7,715, 16, 17. Towers 7,715, 14, 13 do not check as well, because tower 7,714 has a resistance of only 8.5 ohms as compared to 11 to 14 for the other towers. The ground currents in towers 7,714 and 7,716 are in inverse ratio to their resistances. In the example resistance at towers removed from the stricken tower have been assumed considerably lower than the stricken tower on account of the slow rising current fronts. To simplify calculations all resistances are made equal except at the stricken tower which is twice as great. In stroke 3, contact actually was made to the ground wire between towers 7,715 and 7,714. However, the distribution of currents is such that it must have occurred within 10 to 50 feet of tower 7715. The stroke current amplitude, therefore, is between 46,000 and 48,000 amperes with an approximate wave shape of 2×50 microseconds. Similar calculations can be made for the other strokes. It can be seen from Figure 1 that the voltage at the stricken

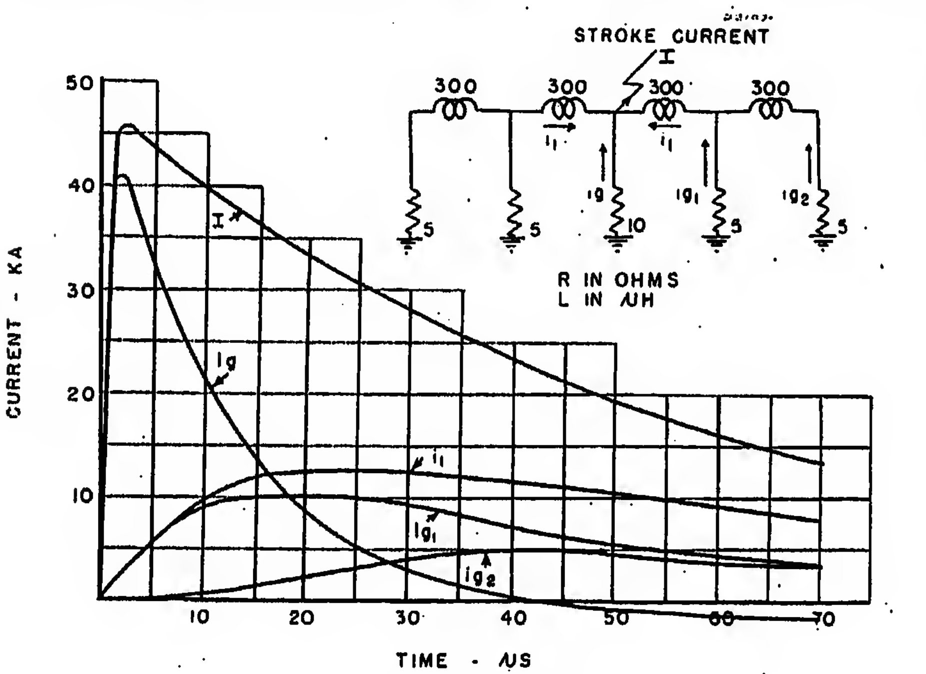

Figure 1. Current wave shapes in ground wires and towers for a 2 x 40 lightning-stroke current to a tower

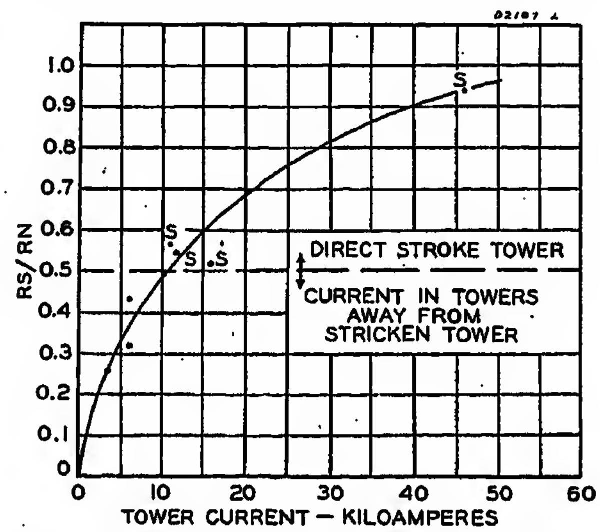

Figure 2. Ratio of surge resistance to normal resistance—R_S/R_N of towers as function of tower current amplitude

Data from Table XVI of the paper. *S* indicates stricken tower

tower ($I_g \times R$) is of very short duration (2×9.5), and therefore the sparkover of an insulator string would occur at approximately 20 per cent to 30 per cent higher voltage. This fact has been made use of under paragraph *4*.

7. In Table XVI, the authors give the results of an attempt to calculate the reduction of ground resistance with increase of tower potential calculated from the product

as shown by Figure 1. Figure 2 shows the effect of the proximity of the stroke to a tower. Incidentally, it also shows the entirely unexpected increase in surge resistance with current amplitude.

(*c*). Combination of very high and low ground resistances. Ground resistances of the order of 1,000 ohms must not only be subject to seasonal variations to a great extent, but also should react differently to surge currents from grounds of 75 ohms or less, decreasing probably the resistance by profuse arcing across the ground surface, or down toward the water level. Test results with steep

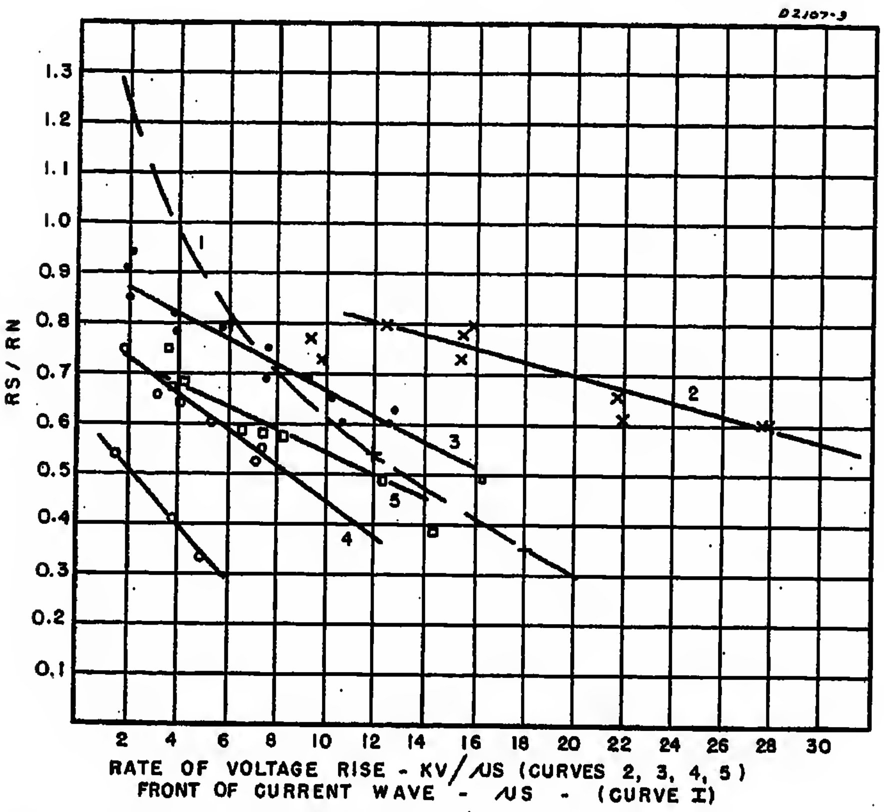

Figure 3. Effect of surge-current front on the ratio of surge resistance to normal resistance—R_S/R_N of a ground

R_S/R_N function of voltage rise

$I_t \times R_N$, where I_t is the measured tower current and R_N the measured Megger or a-c resistance of the ground. From this, they derive an equation and the curve of Figure 2 of the paper. I wish to point out that this curve is much too optimistic, because it says, for instance, that for a ten-ohm ground resistance, a tower current of 1.2×10^6 amperes would cause only 600 kv. Likewise, a tower current of 150,000 amperes and 100 ohms ground resistance would produce a tower voltage of only 600,000 volts and therefore would not cause arc-over of an insulator string of (10) insulators, spaced $4^3/_4$ inches. This is, of course, too much to hope for and is contradicted in the paper by stroke 6, where 56,000 amperes through a ten-ohm ground resistance flashed over three insulator strings. The curve shows these high reductions for three reasons.

Table I

Ratio of Currents	Towers 7,715 7,716 7,717 Measured	Calculated From Figure 1	Towers 7,715 7,714 7,713 Measured
i_g/i_1	3.15	3.22	2.24
i_g/i_{g1}	3.25	3.97	1.96
i_g/i_{g2}	9.1	9.3	4.6
i_{g1}/i_{g2}	2.8	2.34	3.42
i_1/i_{g1}	1.03	1.23	0.88

(*a*). The assumption of a geometrical multiplication factor of 2.5 for the tower to probe potential. Such a factor should vary considerably for each tower and each stroke. Based on stroke 10, with arc-over of three insulator strings at 4,400, this factor at that tower should be of the order of 6.

(*b*). All tower resistances are treated alike and no differentiation is made between stricken towers, where the wave fronts are steep, and towers removed several spans, where wave fronts are slow

Curve	Grounds	Table	References	Current Front—Micro Seconds
2	*C, D*	II	3, I	6

5	*M*	VI	3, II	8–12

Curve 1—R_S/R_N as function of current front at 12.6 kv per microsecond

current waves are limited.[1,2] These few tests show that the steepness of the current fronts has a great effect on the impedance of a ground. Bellaschi's tests[3] which were made with fronts of 6 to 18 microseconds can be interpolated as shown on Figure 3, indicating that, even at low rates of voltage rise across the ground for short ground rods, the impedance of the rod for a 2-microsecond current front is of the order of 1.4 times the a-c resistance. This, of course, checks with the flashover of tower 7,721, stroke 6, and numerous other flashovers occurring to low-resistance structures.[4,5]

J. G. Hemstreet, W. W. Lewis, C. M. Foust: J. R. Eaton has commented on soil conditions in the region of the lines investigated. Because of his close association with this work at the time the ground rods were driven and the attention he has given to soil and geology in this region, his comments are particularly pertinent. His point that ground rods in sandy soil, even though deeply driven provide a relatively high-resistance ground, should be especially noted. Low resistance is provided only when the rods penetrate the underlying clay layer.

Hamilton Treadway calls attention to the fact that this paper did not shed light on the time impedance characteristic of the ground electrodes during the lightning stroke. Of course, as he points out, our methods of measurement wherein only peak currents and voltages were recorded did not provide oscillographic results. Co-ordination of peak currents and voltages is not directly obtained from the data.

However, general experience has shown quite conclusively that the most important factors contributing to tower potential are current amplitude and footing resistance. A high initial impedance potential does not seem to be an important factor in the average circumstance of insulator flashover. In other words, the inductive potential occurring with the initial rise of current is indicated by measurement to be considerably less significant than the ohmic potential of the earth adjacent to the tower footings.

Mr. Hagenguth suggests that we could obtain considerably more information from the data than have been given in the paper. Undoubtedly this is true; however, studies of lightning on transmission lines have, in the past, more frequently been characterized by overreaching interpretations than by "too careful" ones. Our own efforts have been to stick as closely as possible to the data with simple and direct analyses. We try to measure currents and voltages in various parts of the line structure and to relate these to each other in such manner as to achieve as consistent a picture as possible. Our continued examination of structure measurements has in most cases given us a consistent picture when we consider only resistances, resistance voltage, and current summations. This method of analysis is particularly applicable to local conditions within a few towers of the lightning stroke.

With regard to seasonal changes in counterpoise resistance, considerable variation is indicated by the figures of Table II of this discussion.

At tower 7,720, which is next to 7,721, discussed by Mr. Hagenguth, the maximum variation is 420 to 220 ohms. At other towers variations are high as 6 to 1.

Mr. Hagenguth calls attention to the flashover we reported at tower 7,721 although the *IR* product was only 560 kv. Actually we are uncertain of the occurrence of this flashover. The report from the field read as follows:

"Links taken from the *N*-14 line were magnetized without the line tripping out, so we cannot give much information on how the transmission system was affected by this particular stroke of lightning, except the insulators on tower 7,721 show indications of recent lightning flashover."

Mr. Hagenguth's interpretation of wave shapes from crest current readings and on the basis of injection of a representative wave shape is interesting but may involve too much assumption. With regard to his comment on our Table XVI and Figure 2 showing the relation between normally measured resistances, lightning-current resistances and tower potentials, he points out that we are much too optimistic because a ten-ohm resistance, and a tower current of 1.2×10^6 amperes would cause only 600 kv, or 100 ohms and 150,000 amperes would give the same voltage whereas for stroke 6, 56,000 amperes and ten ohms flashed over three insulator strings. The latter case is that of tower 7,721 referred to above where no tripout occurred, and the indication of three-phase flashover is, therefore, unlikely to have been associated with this record. With regard to the optimism of the curve of Figure 2 of the paper, our experience on this line to date does not indicate that it is overly optimistic. The method of interpretation we have included in the paper seems to us to be direct and logical. Undoubtedly additional data will permit of more exact location of the curve.

Table II. Resistance Measurements of Right-Angle Counterpoise

	Resistance—Ohms Tower				
Date	7,660	7,670	7,680	7,712	7,720
6—1937..	225	350	600	540	420
7—1937..	168	250	330	320	232
11—1937..	155	230	310	350	250
10—1938..	1,200	300	300	400	350
7—1940..	175	270	350	350	400
6—1941..	190	240	350	425	300
10—1941..	125	170	235	275	220

Information on tripouts generally confirms our analysis. Confining our attentions to the experimental section of the *N*-14 line of six high-current disturbances, only one had an associated tripout. This was at a location where right-angle and parallel counterpoises were installed, and resistances were several hundred ohms. All five others were at locations where deep-driven rods reduced measured footing resistances to 13 ohms or less. On the *T*-20 line four tripouts were reported for the eight lightning strokes, and these corresponded in all cases with high-resistance towers not equipped with ground rods.

Mr. Waldorf has asked if the data give any indication that rods or counterpoise are the more effective in the prevention of flashover. Now the answer to this question should be based on directly comparable data on a flashover basis, but with each grounding method functioning independently; these data we do not have. However, we did assume in planning these measurements that, with both types of grounding connected, the relative amounts of pickup current would indicate relative performance, and this is what we are reporting in this paper. However, it is important that the results we are reporting be regarded for the time being as pertaining to the particular and peculiar high-resistance soil condition prevailing in our test section. Based on quite limited data, however, some indication of an answer to Mr. Waldorf's question might be derived from tripout experience on the *N*-14 line for the six strokes reported. Strokes 2, 3, 4, 5, and 6 were to sections equipped with deep-driven rods and were not accompanied by tripouts with the possible exception of stroke 6 at tower 7,721, as explained in our reply to Mr. Hagenguth. Stroke 1 to a right-angle parallel counterpoise section, however, did result in tripout which was not mentioned in the paper. No flashed insulators were reported. The rods seem to have the best of it on this basis.

P. L. Bellaschi suggests that the lightning field data presented in this paper could, with advantage, be compared to laboratory results reported in item 8 of the list of references appended to the paper. The authors appreciated this in the preparation of the paper and believe the natural and artificial surge results are in general agreement. In Mr. Bellaschi's laboratory results the ratio of "normal" to "surge" resistance was much lower than the extreme of 25 to 1 found in the case of natural lightning. However, his low ratio applies to a soil of better conductivity than the sand in the region of this experiment. As regards the importance of inductive potential along the tower and in the long ground rod, field measurement experience does not indicate this to be of major importance in the building up of flashover potential. In some of our early measurements a section of tower length some 40 feet long was bridged by a crest voltage-indicating instrument, for the purpose of measuring voltage difference along the tower. Ninety per cent of all measured voltages were below 40 kv with many cases of no voltage registration (below 10 kv) where high tower currents were recorded. Accordingly, inductive potential along the tower has not been emphasized. With regard to conclusion 3 of the paper to which Mr. Bellaschi refers, as having bearing on this matter, the time displacement between counterpoise currents and rod currents has to do with the longer current path through the deep-driven rods (some 100 feet) into the low-level conducting strata and out to remote portions of the induced earth field. Insofar as this displacement represents inductance, Mr. Bellaschi's comments are pertinent.

Abnormal Currents in Distribution Transformers Due to Lightning

Discussion and authors' closure of paper 42-109 by J. M. Bryant and M. Newman, presented at the AIEE summer convention, Chicago, Ill., June 22–26, 1942, and published in AIEE TRANSACTIONS, August section, 1942, pages 564–8.

M. C. Westrate (The Commonwealth and Southern Corporation, Jackson, Mich.): This paper presents a very interesting approach to the problem of fuse outages on distribution transformers in the theory that surge currents saturate the core and thus allow abnormal power current to flow through the primary winding. This may be the answer to much of the trouble experi-

enced with fuse outages during lightning storms and merits further consideration.

The point made by the authors in regard to lightning strokes producing large currents in the secondary windings of the transformers may be theoretically possible, but it is doubtful if this is a very frequent occurrence or a serious factor in the failure of distribution transformers.

D. D. MacCarthy (General Electric Company, Pittsfield, Mass.): Messrs. Bryant and Newman have analyzed the effect of long-duration surges on grounded neutral distribution circuits and concluded that these surges on the primary lines are one cause of primary fuse blowing. This is supported by Figure 3 in the paper showing that in service fuses were blown on a single-phase rural line only at locations where the primary currents were the largest. The authors state that the primary currents may become relatively large when the core of the transformer becomes saturated, and a step-by-step calculation is given for a three-kilovolt-ampere 7,200-volt transformer which is based upon the transformer design constants, the magnetization curve, and an assumed surge of 55 kv crest decaying exponentially to half value in 2,500 microseconds.

This conclusion regarding the current in the transformer primary agrees with results obtained in Pittsfield during investigation of the effects of long-duration surges made soon after the first actual oscillographic measurement[1] of long-duration lightning strokes to the Empire State Building in 1937. As a part of this study tests were made on a three-kilovolt-ampere, 6,900-115/230-volt distribution transformer of 3.38 per cent impedance. Surges were applied to one high-voltage terminal of the unexcited transformer from a 56 microfarad impulse generator charged to voltages of 20 or 50 kv; the other high-voltage terminal of the transformer was grounded. Representative oscillograms with the transformer secondary winding open-circuited are shown in Figure 1 and in Figure 2 of this discussion with that winding short-circuited. The crest values of primary current and voltage were about the same, irrespective of whether the secondary winding was open-circuited, short-circuited, or was connected to a resistance corresponding to a full load. When the secondary winding was open-circuited, or with it closed on full-load resistance, the primary current does not reach an appreciable value until the iron becomes saturated. This time to saturation, discussed by Bryant and Newman, can be seen in Figure 1 of this discussion. When the transformer secondary winding is short-circuited, there is no delay in the starting of the primary current, since the currents in the two windings give equal and opposite magnetizing forces. In this case the initial rate of current rise is governed by the leakage inductance of the transformer as might be expected.

Other tests were made with impulse voltages as high as 40 kv applied to the transformer primary winding. In these tests fuses rated three amperes could be blown by one discharge.

Transformer inductance was calculated from the current and voltage oscillograms and is found to drop from the magnetizing inductance of 1,400 henrys to about 2.5 henrys for primary currents of 50 amperes and approach the leakage inductance of 0.9 henry with primary currents of 125 amperes. Values of primary resistance were calculated from the voltage at the crest of the current discharge and were found to be five to 30 per cent higher than the d-c resistance, presumably because the core and eddy current losses appear as a resistance.

After having studied the transformer characteristics, the effect of long-duration surges on single-phase grounded neutral circuits was investigated through the use of model lines and calculation. The results obtained from one of the conditions studied are shown in Figure 3 of this discussion in which a long-duration stroke of 500 amperes constant current was assumed to strike the phase wire at the mid-point of a 6,900-volt distribution line, 40 miles in length. It was assumed that there was one three-kilovolt-

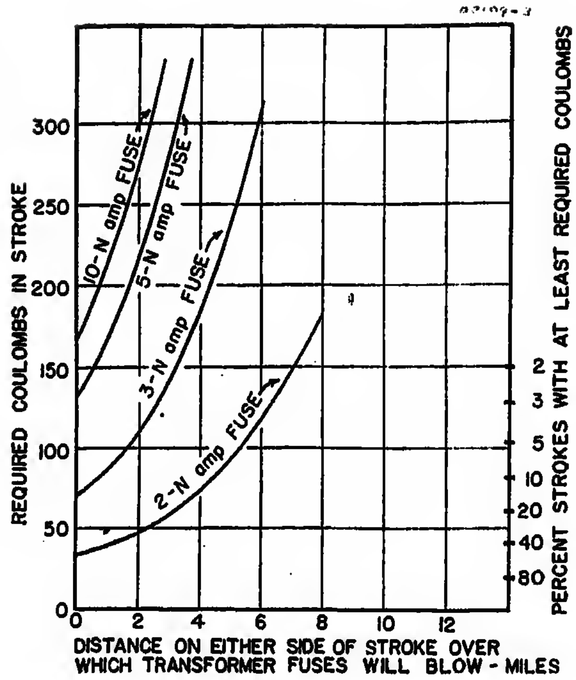

Figure 3. Coulombs required to blow fuses of three-kilovolt-ampere 6,900-volt transformers connected to single-phase grounded neutral line 40 miles in length. Stroke of 500 amperes assumed to strike phase wire at mid-point of line

ampere distribution transformer per mile and that the line was fed from a 60-kva substation transformer. The voltage between the line conductors at the stroke location was assumed to be limited by a valve-type lightning arrester.

Curves plotted in Figure 3 of this discussion show the stroke charge required to blow fuses of several different ratings as a function of the distance in either direction from the mid-point of the line where the stroke occurred. The right-hand scale shows the percentage of strokes expected to have charges at least as great as read from the left-hand scale based upon lightning data[1] from the Empire State Building. The distribution transformers and fuses were assumed to be the same for each location. There are a number of factors in service which will affect the locations where transformer fuse blowing will occur. Among these are differences in the characteristics of the fuses, distribution transformers, variations in resistance of the grounds along the line, and the possibility that flashover may occur between the line conductors due to the high current peak of the lightning stroke which generally precedes any long-duration low current component that may occur. However, these curves lead to the conclusion that fuse blowing on such a line will be restricted to the vicinity of the stroke and that the number of fuses blown decreases very rapidly as the fuse rating is increased. The impedance of the distribution line and the density of connected transformer kilovolt-amperes greatly influence the number of fuses that can be blown. The high impedance and light load of the line considered in Figure 3 of this discussion are favorable to fuse blowing by long-duration surges. Yet with five-ampere fuses only three per cent of the strokes that occurred to the Empire State Building have sufficient charge to blow the fuse of the transformer at the stroke location.

As Bryant and Newman state, more data are needed to establish the frequency with which long-duration discharges blow transformer fuses in service. This frequency

must, of course, be established in order to judge the permissible cost of any solution proposed. It is difficult to determine the portion of fuse blowing that is caused by long-duration discharges. Probably the most complete compilation of operating data on distribution transformer lightning protection was prepared by L. G. Smith[2] based on reports from approximately 40 utilities covering urban and rural territories for a period of three years; with conventional arresters and solid interconnection, the rate of fuse blowing was 1.85 per cent for urban and rural territory combined in Table X, and 6.26 per cent for rural territory only in Table XI. Some undetermined part of this fuse blowing was probably caused by lightning currents flowing in the transformer primary windings.

In looking for means of preventing impulse currents from blowing primary fuses, the author of this discussion and his associates developed a fuse with a small series inductance and a protective gap shunting the current responsive element of the fuse link and inductance. A number of years ago, a trial lot of these fuses was installed for experimental purposes on the line side of arresters protecting distribution transformers in order to gain service experience. The number of these special fuses blown by the relatively high impulse currents discharged by the arresters was much less than for standard fuses, see Table VI of reference 3. However, it was concluded that the combination of series inductance and shunting gap is relatively ineffective in preventing such fuse blowing as may occur because of lightning currents building up in the transformer primary winding, because, with any practical fuse design, the shunting gap will not spark over on account of the slow rate of current rise. Furthermore, should the shunting gap spark over because of a pulse of current through the transformer capacity, it will seal and long-duration current that may subsequently build up through the transformer primary winding will flow through the fuse element.

Only strokes to the primary lines are mentioned by Bryant and Newman. However, the effect of strokes to other parts of the circuit was investigated by the author of this discussion, and it was concluded that primary fuses can be blown by long-duration strokes to the secondary wires or to the earth near the ground connections at the transformer pole or on the secondary circuit. Unquestionably some portion of fuse blowing is due to strokes that do not reach the transformer over the primary circuit.

J. H. Hagenguth, H. C. Stewart (General Electric Company, Pittsfield, Mass.): We wish to discuss the first part of the paper describing the failure and deformation of the low-voltage winding of a distribution transformer. A few such cases, as described in the paper, have come to our attention. The number is so insignificant compared with transformers in service that in all probability it would not be economically justified to provide protection.

The authors point out that, "such conditions, to a greater or lesser extent, must occur in almost every case of a direct stroke to line near a transformer installation."

It is, of course, immaterial whether the stroke contacts the neutral wire directly or by way of the high-voltage line wire and the arrester. Some brief calculations have been made to show that the possibility of the occurrence of such phenomena should be extremely rare. Figure 4 of this discussion shows the circuit used as basis of the calculation, which represents the condition of a transformer installed on a line where the nearest transformer is at least five miles removed. This is, of course, purely hypothetical but represents the most severe condition possible, because practically all the current in a stroke has to be conducted to ground at that location. The secondary neutral lead is represented by an inductance based on 0.55 microhenry per foot. The inductance of the two secondary-line leads are assumed to be in parallel and therefore half the value of the neutral wire. (Since all three wires carry current in the same direction and are closely spaced, these inductance values are not mathematically exact, but they are of the right order.) The use of the inductance is justified, because after only a few reflections, the surge impedance of the wires changes into an inductance.

The solid curves of Figure 4 show the current amplitude through the secondary winding in per cent of the total current at the neutral wire, when the service pole ground is 30 ohms, as function of the resistance of customer's ground. All ground resistances are effective resistances. The dashed lines show the currents for ten-ohm pole ground. Stroke current wave shape used for calculation is 0×00.

The authors assume that damage to the transformer shown in their Figure 1 was probably caused by a current of 20,000 amperes in each section. If we assume even one quarter of that value through one section or 10,000 amperes through both sections, the three horizontal lines indicate the levels at which 10,000 amperes would flow through the secondary for different stroke currents as indicated at the first right-hand scale.

McEachron and McMorris[1] have shown that the currents through distribution arresters are of relatively low value, the highest measured current from 1,608 records was 25,000 amperes (six records or 0.003 of the records indicated values in excess of 25,000 amperes). The percentage and expectancy figures given in their Figures 1 and 2 are shown on the right-hand scale of Figure 4 of this discussion. Curves 1, 1A, 2, 2A, and 3, 3A are drawn for 600-, 100-, and 50-foot long secondary lines between transformer and customer, respectively.

Figure 4 shows clearly that the chances for even 10,000 amperes through a distri-

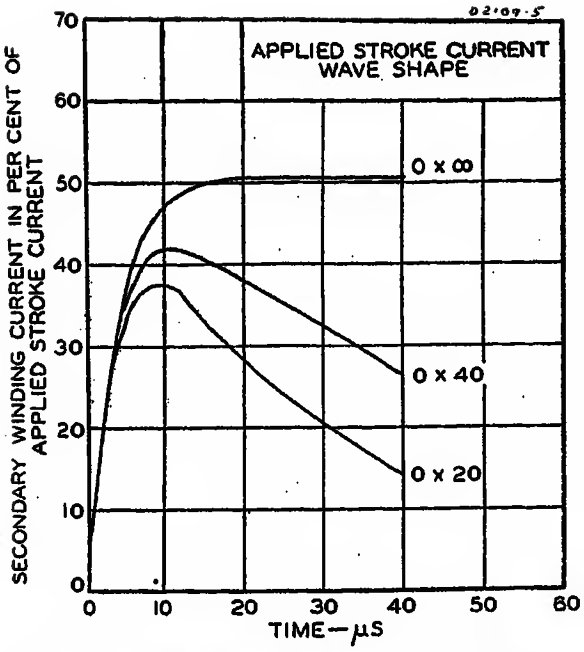

Figure 5. Effect of wave tail of lightning-arrester currents on amplitude of secondary winding currents

$R_1 = 30$ ohms, $R_2 = 5$ ohms, 600-foot extension (See Figure 1 for diagram)

bution transformer secondary winding are very small even for the isolated transformer location calculated.

As was pointed out by the authors, the probability of high currents through the secondary winding is rapidly reduced as the service pole ground resistance decreases below customer's ground resistance.

However, this is a solution that should hardly be recommended because of the associated hazards. The resistance at the customer should be kept to as low a value as possible. Figure 4 of this discussion shows that even with 0 ohms resistance at the customer and 10 ohms or 30 ohms at the pole, high currents through the secondary winding are improbable.

The circuit shown in Figure 4 neglects the resistances of the secondary leads and windings. Since the inductances and resistances are relatively small, current flow quickly is distributed according to resistances rather than inductances. The equations for circuit of Figure 4 which are of the form $A(1-\epsilon^{-nt})$ were used because they readily can be evaluated for crest current. The effect of resistances is similar to that of the inductances, and therefore a current time curve is practically the same for both conditions.

There is a very good reason to believe that current peaks to distribution systems are of relatively short duration, perhaps not longer than 40 microseconds, and consequently the duration of the secondary winding currents would be reduced correspondingly to shorter durations. The effect of the length of the current wave is most pronounced for conditions of highest currents through the secondary winding. Figure 5 of this discussion shows the current wave shape through the secondary winding for rectangular tail, 40-microsecond tail and 20-microsecond tail of the current wave through R_1 and R_2 of Figure 4. The marked reduction in current crest is evident.

The wave tail of the current through R_1 and R_2 is determined to a considerable extent by the presence of other pole and customer grounds near the location struck by lightning. The effect of two adjacent grounds on either side, 1,000 feet and 5,000 feet distant, is shown on Figure 6 of this discussion. Again the primary neutral lines are represented by inductance and infinite long stroke current wave is assumed. The current $i_1+i_2+i_3$ is rapidly reduced to half value, even for 5,000-foot distance between grounds. Therefore, the duration and the amplitude of secondary abnormal currents are definitely limited. (This calculation neglects the inductance between stricken pole and customer. The ground resistance at the two far poles are assumed to be normally 30 ohms reduced to half to take account of resistance reduction[2] caused by impulse currents on account of the slow current fronts and customer's ground at their locations.)

From this brief study, it is shown that secondary winding currents of sufficient amplitude to damage the secondary winding in the way shown in the paper are hardly to be expected if the stroke contacts the primary neutral wire, although the possibility exists.

There is, however, a good possibility that damage of this type is caused from strokes contacting the electrical wiring at the customer's premises and due to high ground-resistance current flows from customer's wiring to the service pole. The higher the customer's ground resistance, the greater, of course, is the possibility of damage to the secondary winding, because there are no other additional connections which may drain the bulk of the lightning stroke current.

Three cases are known to us where lightning entered a distribution system through the secondary circuit without even then causing this particular damage. One is described in another paper.[3] In this case, the energy of the stroke was carried to ground through three different grounds.

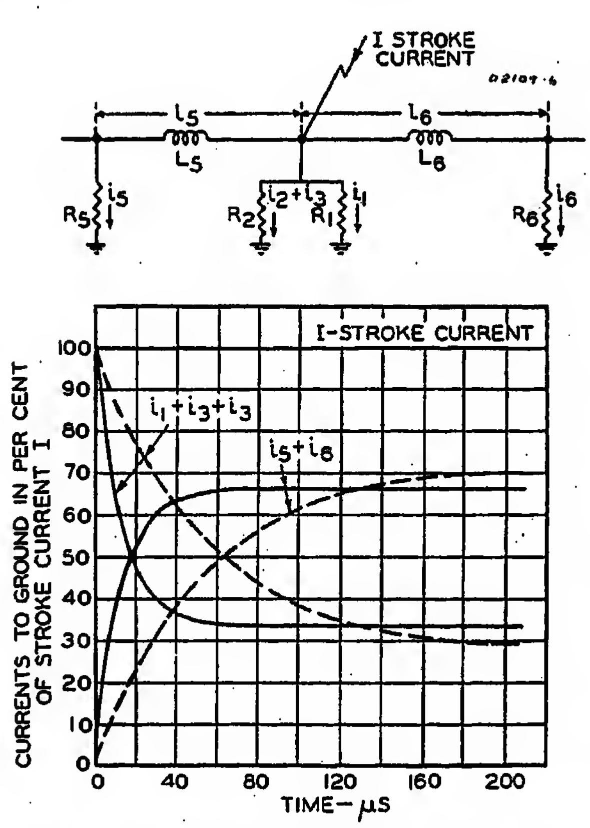

Figure 6. Reduction of length of current tail at point of stroke contact because of grounds at adjacent poles

Primary neutral wire inductance

$L_5 = L_6 = 554$; 2,770 microhenrys

Distance $l_5 = l_6$ between service poles

1,000; 5,000 feet

Ground resistance $R_5 = R_6$ 15; 15 ohms

Ground resistance $R_1 = R_2$ 30; 30 ohms

Another case occurred in the city where the customer was grounded to the water system and a third at a Civilian Conservation Corps camp in wooded country.

The greatest exposure to such damage should be expected on rural lines where the primary neutral wire is grounded at perhaps only a mile interval. The principal protection as shown by the curves of Figure 4 would be low service pole ground resistance and short secondary leads with customer's ground at a minimum economical value.

E. E. Piepho (The Detroit Edison Company, Detroit, Mich.): During every lightning storm there are a few mysterious cases of blown primary fuses on distribution transformers, with no evidence of flashover or other failure on the transformer side of the fuse. Bryant and Newman's proposition that such events may be caused by long-duration lightning strokes which establish sufficient surge current through the primary winding to blow the transformer fuses, appears a likely possibility. This situation has not been serious in the past, because we have generally avoided the use of low-current fuses, the five-ampere size usually being the smallest. Admittedly, this minimum size does not protect the smaller distribution transformers from secondary faults or even winding short circuits, but it serves the larger purpose of isolating a transformer in serious trouble from the rest of the circuit. Anyone undertaking to use low-current fuses, rated to provide complete transformer protection, may expect an appreciable increase in fuse blowings from electrical storms.

Two years ago, when Bergvall and Beck presented their paper on "Lightning Protection of Distribution Systems," the writer suggested that their treatment of the subject indicated that we might have to revise some of our thinking regarding protection of electric equipment and distribution circuits, in accordance with the new conception of long-duration lightning discharges. A wholesale blowing of customer branch fuses in one locality during a lightning storm was cited at that time, and it was indicated that long-duration lightning discharges into secondary wiring by way of the transformer connections may have been the cause. Bryant and Newman's paper offers good proof that this may occur.

Recently, we experienced an interesting case of lightning damage to the operating mechanism of a street-lighting time switch. From tests we have made we know the insulation level of the low-voltage operating mechanism is approximately 4,000 volts, which is rather low considering the degree of lightning exposure. We devised adequate lightning-arrester protection for this insulation, but a severe electric storm recently demonstrated an unlooked-for weakness.

Paralleling the low-voltage arrester there was a sneak circuit through the high inductances of the series field and armature of the time switch motor. We expected little or no surge current through this branch because of its high inductance; nevertheless, the motor field and armature windings were burned open in one switch. The insulation of these windings to ground was tested and found unimpaired. Our belief is that a long-duration discharge through the arrester could have established enough current through these low-current windings to burn them open.

Edward Beck (Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa.): Bryant and Newman discuss an aspect of lightning on systems which is of particular interest on the lighter rural distribution circuits, since it contributes to outages where the fusing is light. One phase of this general subject has been discussed in the Bergvall and Beck paper mentioned by the authors, the phase dealing with the effect on arrester duty, which is relieved by the currents that flow through the transformers. The Bryant and Newman paper deals with the transformer currents and their effects on the transformer and the fusing. Considering the capacities of the smaller standard fuses, such as the two-ampere links mentioned by the author, for carrying current without damage, it is not surprising that the surge currents blow them occasionally. The danger of primary fuse blowing is diminished with increasing rating. This is almost axiomatic, and it has been shown by statistical data.

It is practically impossible to fuse small transformers on the primary against overload or secondary short circuits and maintain a satisfactory degree of reliability and service continuity. Attempts to accomplish this with conventional fuse links has led to two types of fusing. The first of these is to fuse with small links in an effort to prevent transformer burnouts from overload. This type of fusing leads to a large number of outages caused by blowing of the links from secondary fault, lightning currents, and mechanical damage. The second type of fusing is to select links based upon secondary short-circuit currents. The larger links resulting from this type of fusing reduce the number of operations to some extent from the causes mentioned above but at the expense of possible burning out of the transformer from overload and short circuits remote from the transformer. The economics appear to favor the second type, and there is a definite trend towards this type of fusing by operating companies. There is another type of overcurrent protective system which provides both overload and short-circuit protection to the transformer and at the same time eliminates unnecessary interruptions of service. This method employs a thermally controlled secondary breaker mounted inside the transformer. By having the breaker operation based upon transformer winding temperature, protection of the transformer is afforded for all types of overcurrent conditions, and at the same time it is possible to take advantage of the inverse time temperature characteristics of the transformer to adjust the breaker so as to eliminate most of the interruptions in service encountered through the use of small fuses.

There is now a large amount of service experience available with these types of overcurrent protection, and it would be of interest and value both to operators and to manufacturers to have comparative operating data published.

J. M. Bryant and **M. Newman**: The writers are pleased that the paper has led to considerable discussion. D. D. MacCarthy's comments and oscillograms on long-duration currents and fuse failures are interesting and in complete agreement with our work. As a matter of fact we have recorded almost identical oscillograms to those given by MacCarthy, which were, however, not included in this paper as they fitted in more directly in a series of papers on "Fuse Failures Due to Lightning," published by the engineering experiment station, of the University of Minnesota. We were interested to learn that MacCarthy and his associates have had some favorable field experience with a series inductance and shunt gap arrangement of protection of fuses against surge outages, as we had investigated such a scheme proposed a number of years ago by R. R. Pittman of the Arkansas Power and Light Company. It was established on first consideration that such a scheme by itself functions primarily to by-pass around the fuse the initial current surges due to the transformer capacitance under conditions of rapid rate of rise of surge voltage. The long-duration currents penetrating the transformer windings were eliminated as a factor in fuse blowing in several different ways, such as some special saturation by-pass schemes, and proper design of heat storage capacity of the links themselves. The theoretical background on fuse failures because of lightning is presented in the experimental station bulletins referred to above. Field experience is being collected on the simplest combinations of the various methods of surgeproof fuse design.

The use of secondary breakers, as brought up by Edward Beck, is a perfectly good way of preventing lightning-fuse failures, in that it side-steps the problem by making the primary fuse so large as not to respond to surges, and thus to remove the transformer only if it is already damaged, while depending on breakers on the secondary side for overload protection. We have been carrying on some researches to help solve the surge problem in relation to fuses from the point of view that as fuses are being used in any case, to isolate the transformer from the line after burnout, it would perhaps be more economical if they also protected the transformer.

The discussion by J. H. Hagenguth and H. C. Stewart gives a very interesting approximate theoretical estimate of the extent to which other cases of damage of secondary windings may occur. We do not, however, quite agree with attributing a greater possibility of such cases from strokes on the secondary side, since under such circumstances the paths to ground from the transformer case neutral grounding point is the same anyhow, and there is a much greater probability that the stroke would short-circuit the low-voltage leads together so that the transformer windings would be bypassed. While on the subject of strokes on the secondary side, it is of interest to note that it may be possible for surge currents to build up in the secondary winding after the manner of the abnormal currents in the primary winding discussed in the paper. Such build-up would be generally accompanied by sufficient voltage to induce an arrester flashover and primary fuse failure; several such cases have been observed. The case of secondary-winding damage in the paper is, however, definitely due to current entering the winding from the neutral connection, as shown by the opposing directions of twist of the winding sections.

The comment by M. C. Westrate on the desirability of further investigation of effect of abnormal power current on fuse failures under surge transformer saturation conditions seems to us to be well worth emphasizing. The discussion by E. E. Piepho brings out several interesting cases of lightning failures that might be readily accounted for, as he points out, by such analysis as presented in the paper. The writers in conclusion are pleased to note particularly that the discussion has been constructive in leading to further extension of these investigations in the field.

Induced Voltages on Transmission Lines

Discussion and authors' closure of paper 42-103 by C. F. Wagner and G. D. McCann, presented at the AIEE summer convention, Chicago, Ill., June 22–26, 1942, and published in AIEE TRANSACTIONS, 1942, pages 916–30.

W. W. Lewis (General Electric Company, Schenectady, N. Y.): The authors have prepared an excellent and exhaustive paper on the subject. I wish to discuss a few points:

Figure 28 of the paper shows distribution curves of crest current in lightning strokes as determined by various investigators. In the text it is stated that the maximum current which has been reliably measured is 160,000 amperes. This refers to a Fulchronograph measurement of a stroke to a stack at Anaconda, Mont., and in reference 10 of the paper it is stated that this represents the highest known magnitude in which the total current was measured at one point, as contrasted with measurements obtained by summing up currents in parallel paths.

We have shown in several papers[1,2] reasonably good agreement between total current and the summation of individual currents in parallel paths, and, considering, the wide tolerance necessary in this class of measurement, we believe such estimates to be as reliable as those made by any other method.

In 1934 on the Glenlyn–Roanoke 138-kv line of the Appalachian Electric Power Company, measurements were made by magnetic links of a stroke with an estimated total current of 218,000 amperes negative polarity. This current was the summation of the currents in all the towers affected by the stroke, seven towers in all.[3] The maximum current measured in any one tower is 132,000 amperes obtained on the Philadelphia–Delaware River 66-kv line of the Philadelphia Electric Company in 1935. This was also the total current in the stroke.

Another stroke in the same year on this line totalled 156,000 amperes in two towers. Magnetic link measurements have indicated 146,000 amperes in the broadcasting tower of station *WABC* and 156,000 amperes in the tower of the Empire State Building.

In Figure 28 of the paper a curve by Waldorf is shown, giving distribution of crest current in lightning strokes, and reference 15 in the paper is given, presumably for the origin of this curve. Waldorf's original curve (Figure 1 of reference 15 of the paper) shows the distribution of 1,201 current measurements in *towers* and does not give total stroke current. We believe therefore that this curve should not be included in Figure 28, which deals with total stroke currents.

The authors state: "There are very little field data on lightning surge voltages for which the induced voltages can be segregated from those produced by direct strokes." In 1929 at the Wallenpaupack laboratory, 95 cathode-ray oscillograms were obtained of voltage surges on the line. Of these 50 measured under 100 kv, 30 measured between 100 and 300 kv, and 15 measured above 300 kv. Data on the 45 oscillograms above 100 kv are given in reference 4 of this discussion. In the same year at Newcomerstown, ten oscillograms were obtained ranging from 55 to 245 kv. Data on these are given in reference 5 of this discussion. In 1930 at Cherry Valley oscillograms of 23 surges were recorded. Data on these are given in reference 6 of this discussion.

It is very reasonable to assume that the low-voltage positive polarity surges are induced. Peek has classified the 1929 surges as coincident with trip out and not coincident with trip out and has assumed that the latter were induced.[7] It would seem that there is a wealth of untapped information in these oscillograms.

The curves of the paper indicate an increasing induced voltage with decreasing distance between the conductor and the projection of the stroke. Suppose the stroke hit the overhead ground wire, perhaps ten feet or so away from the conductor. How would this work out as far as the induced stroke is concerned?

E. R. Whitehead (Duquesne Light Company, Pittsburgh, Pa.): During the first few years of field investigations of lightning on transmission lines with the cathode-ray oscillograph, it was my pleasant duty patiently to await the occurrence of induced voltages caused by the release of bound charges on the line conductor. Despite the fact that many strokes were observed to strike the earth quite close to the line, very few oscillograms were obtained, and these were of low magnitude.

Fortescue and Bewley showed that the principal reason for the low induced voltages lies in the current-time characteristics of lightning, and both assumed the charge concentrated at a point in the cloud. Wagner and McCann have applied their knowledge of the lightning-stroke mechanism in an exceptionally lucid manner to show how the actual distribution and neutralization of charges may be utilized to calculate induced voltages much more accurately. I believe their contribution is of great value.

If I interpret the curves of Figures 3 and 11 of the paper correctly, it appears that any stroke which is close enough to induce a voltage of importance on lines at 66 kv and above is very likely to strike the line itself. Now this fact leads to a conclusion not mentioned by the authors and one which I believe may be of importance in practical application.

Positive voltages of the order of 1,000 kv for a 100-kiloampere stroke to a tower would correspondingly increase the potential difference across the insulator string, since the tower would be depressed in potential by the amount of impedance drop in the tower and tower grounding system. The time of voltage crest is such that these voltage-difference components would be additive; hence the net effect is roughly equivalent to that obtained by conventional "direct-stroke" theory if a fictitious resistance of ten ohms is added to that of the tower footing.

The inclusion of this effect may be significant if the tower-footing resistances lie in the range 0 to 50 ohms, and close comparative performance calculations must be made.

Despite certain analytical difficulties, I believe the method presented by Wagner and McCann can be extended to the case of a stroke to the tower or ground wire. Preliminary studies I have made using the same stroke mechanism and L. V. Bewley's method of analysis indicate that such an extension might be the missing link which would give a satisfying aspect of completeness to our theory of lightning effects on transmission lines and dispose of the terms "direct-stroke" theory and "induced-surge" theory.

I should like to call the authors' attention to an apparent discrepancy in the data given by the curves. Most of the curves give a voltage crest of about 1,100 kv for a 50-foot conductor, and a 100-kiloampere stroke at a distance of 150 feet from the line. Figure 29, however, gives 1,100 kv for the same stroke 100 feet from a line of the same height.

J. H. Hagenguth (General Electric Company, Pittsfield, Mass.): The authors have made an excellent study in calculating the induced voltages on transmission lines using the mechanism of the lightning discharge as known from the photographic studies by Schonland (references 4–8 of the paper) and McEachron (reference 9 of the paper) and the oscillographic studies of McEachron and others as the basis of their calculations.

They find that, in general, the gradients are of the order of 100 kv per foot or less, so that basically the calculations of Bewley (references 2 and 17 of the paper) can still be used to advantage in calculations as to the induced voltages. The authors find, however, that the gradients directly at the point struck reach tremendously high values. In Figure 6 of the paper the gradient approaches infinity at $d=0$ as the stroke approaches the ground. Such high gradients, if they would actually exist, presumably should cause flashover every time a tower of a transmission is struck, which, of course, is not the case in practice.

Actually, the induced voltages appear to be considerably below the values calculated. Fortescue (reference 1 of the paper) showed that with a stroke 250 feet from a transmission line, 1,600 feet distant from a cathode-ray oscillograph connected to that line, no voltages could be measured at the oscillograph station. The photograph of this occurrence does not indicate any streamers from the line or from the tower, indicating that the gradients must have been less than 165 kv per foot, which is the critical breakdown gradient in the nonuniform field in air at large spacings (30 feet).

The theory presented appears, therefore, at variance with observations. I question that the calculations of equations 8 and 11 of the appendix are correct when considering a point directly underneath or close to the lightning channel. These calculations are based on the assumption that each charged particle in the uniformly charged channel produced a gradient equal to a point charge at that point. By integrating over the whole channel, the combined gradient is found. In the field produced by a charged vertical line, the effect of the charges distant from the ground on the gradient directly below or close to the path is negligible, and only the charges at the lower end of the channel should contribute materially to the gradients, and therefore the gradients should be considerably lower than calculated.

It appears to me that further point to be considered is the availability of charges on line conductors. These charges can accumulate by leakage over the insulators which is a longtime process associated with the charges accumulating in the cloud. These charges are distributed along the line wire and bound by all the charges in the cloud distributed over the line. While the total bound charge thus may be of considerable magnitude, these charges are not immediately available on the line near the lightning channel. The charges bound in the immediate vicinity of the channel are small, and the charges which can be brought from the distance are limited for two reasons:

1. It takes time to move these charges along the wire.

2. Some relatively short distance away from the channel the effect of the cloud field will be greater than the effect of the field produced by the return stroke, and the charges at those distances will remain bound.

From these considerations, it would appear that high voltages as shown in Figure 12 could not exist on line wires. On ground wires, the voltages at mid-span might be

quite high for very short times, because charges are more readily available. However, even for this condition, flashover can hardly be expected. As shown by practical experience, even direct strokes of considerable amplitude contacting the ground wire at mid-span hardly ever cause flashover at mid-span.

R. H. Golde (The British Electrical and Allied Industries Research Association, London, England): The authors are to be congratulated on having attacked afresh the old problem of the calculation of induced voltages which has so far defied all attempts at a correct solution. I have recently made similar calculations using the same fundamental considerations with only a few modifications which prove, however, as will be shown elsewhere, essential for the numerical solution of the problem.

Before discussing the above modifications it may be pertinent to comment on the apparent agreement between the author's calculations and observed values as presented in Figure 33 of the paper. All the calculations are based on the assumption that the highest induced voltages are due to strokes to earth at a distance of three times the height of the line above ground. This, surely, overlooks the fact that much higher induced voltages must be released in the case of a direct stroke to a transmission tower or earth wire without flashover. As these cases must influence decisively the frequency-distribution curves of induced voltages, the authors appear to have started from wrong assumptions, and the agreement obtained in Figure 33 must be regarded as only fortuitous.

If it be conceded that the highest induced voltages occur in cases of direct strokes to earthed parts of the transmission system, it follows that the horizontal distance between the lightning channel and the nearest line wire is very small. This case leads, however, to excessively high-voltage values by the authors' methods, as can readily be seen if the curves plotted in Figures 12 or 29 are extrapolated to very short distances between the lightning channel and the line. The reason for this breakdown of the method adopted by the authors for the important case of short distances lies in their assumption that the induced voltages are determined only by the charge distribution along the leader channel and by the velocity of the return stroke. This results not only in voltages of several million volts but also in substantially infinitely steep wave fronts of the induced surges. It may be mentioned in passing that, on the authors' assumptions, the wave shape of the lightning current would also have an infinitely steep front with an exponential tail and would not give the normal double-exponential shape as claimed in the introductory section.

The above difficulties are overcome by recognizing that the neutralization of the charges deposited along the leader channel cannot take place instantaneously.[1,2] The authors attack this conception by the calculation given in their Appendix II but, omitting all further criticism of the method adopted, it should suffice to point out that the tip of the advancing return stroke cannot be maintained at zero potential. That part of the channel which is just above the tip of the return stroke is still in electric contact with the cloud and therefore, omitting the voltage drop along the leader channel, is practically at the cloud potential of several million volts. It is physically inconceivable that this potential falls to zero "instantaneously" on contact with the tip of the return stroke, and the transition will actually occur in the course of the few microseconds postulated for the time required for lateral neutralization of the channel charges.

Calculations made with this new conception show that the charge distribution along the lightning channel is not immaterial, as suggested by the authors. It thus follows that the voltages induced in overhead wires are determined by three factors, that is, the distribution of charge along the leader channel, the rate of neutralization of these charges, and the velocity of the return stroke. It may also be added that it seemed advisable to use an exponentially decreasing charge distribution along the channel and a similarly decreasing velocity of the return stroke. If the functions which are suggested for these parameters in the paper quoted above are accepted, the resulting induced surges in cases of strokes to earthed parts of the transmission system are of the amplitude and wave shape to be expected. A full description of the procedure adopted and of the results obtained will be published later.

In addition to the above fundamental observations on the method of calculation, a few specific points may be briefly discussed. Thus the charge deposited along the leader channel is calculated by the authors by assuming a constant current of 100,000 amperes flowing for 65.6 microseconds, that is, the time for the return stroke to reach the cloud discharge center. This assumption can hardly be regarded as valid, having regard to the wave shape of the average lightning current. It follows that the numerical value adopted for the charge along the channel is too large. The authors state, furthermore, that, at the instant when the leader stroke makes contact with the ground, the charge left in the cloud center has decreased to zero. Although this charge does not influence the occurrence of induced surges, it may be mentioned that actually an appreciable amount of charge must be left in the cloud, as shown in the paper quoted above, and also by the low current discharge flowing, even on the authors' assumption, for a considerable time after the return stroke has reached the cloud (see Figure 2 of the paper).

In this connection it was interesting to note that the authors incorporate partly in their Figure 1 the mechanism of successive strokes, as outlined in the paper quoted, which differs from Schonland's originally suggested picture. In particular, Figure 1d accepts the idea that the conducting channel which connects the exhausted charge center in the cloud with earth will become positively charged under the influence of the surrounding negative cloud charges. From this it is difficult to see how the authors account for the interruption of the positive current flow into the channel, as shown in Figure 1e. Though the interesting question of the continuous current flow throughout a multiple lightning stroke has been discussed elsewhere[3], a reply with respect to Figure 1d would be appreciated.

In Table I ranges of return-stroke velocities and their mean values are given for three current ranges. It would be interesting to know on what information these values are based, since I am unaware of any measurements of return-stroke velocities with simultaneous determination of the stroke current.

Finally, one small point in nomenclature may be cleared up. In discussing the question of lateral charge distribution the authors refer to the bright portions of the stepped leader which were observed by Schonland and add that these were called "dart leaders" in the paper mentioned above. Actually these short bright steps were called "darts," whereas the term "dart leader" was used by Schonland to distinguish the leader stroke of successive strokes in a multiple stroke from the "stepped leader," which normally precedes the first stroke to ground.

C. F. Wagner and G. D. McCann: The most accurate field measurements of direct-stroke currents are those for which the total current passes through a single point, such as a mast. The currents in excess of 160,000 amperes, which Mr. Lewis mentions in his discussion, were not measured in this manner but were the result of summing the individual currents in parallel paths. Several cases for which checks could be made between actual current and the summation in parallel paths showed considerable discrepancy in the two results. This point is discussed in more detail in reference 19.

The curve in Figure 28, labeled as Waldorf's, was computed from the original data supplied by Mr. Waldorf and is plotted for the crest magnitude of the total lightning-stroke current and not for tower currents. A comparison between this curve and the curve of Figure 1, reference 15, to which Mr. Lewis refers, indicates that they are not the same.

Lewis and Whitehead have raised the question of the voltage induced on phase conductors by strokes to the ground wire. This case is not considered in the paper. It requires more detailed knowledge of stroke mechanism, especially near the ground terminus, than for strokes to open ground. In regard to the influence of induction upon the voltage across the insulator string, we are not quite convinced whether its effect can be represented by a resistance, and, if so, whether that resistance is ten ohms. Certainly if this effect can be represented by a resistance, it would be a very welcome simplification of the analysis.

The apparent discrepancy between Figures 11 and 29, referred to by Mr. Whitehead, arises from the difference in assumptions for the two curves. The voltages in Figure 11 were calculated for a crest stroke current of 100,000 amperes and a return streamer velocity of 100 feet per microsecond, whereas for the voltage curves of Figure 29 the variation of return streamer velocity with stroke current has been taken into account.

There is little in Mr. Hagenguth's discussion with which the authors can agree. His reference to Fortescue's experience, reference 1, is not inconsistent with the results of the paper. As shown in Figure 29, for a line 100 feet high a stroke 250 feet from the line could have a current crest of 15,000 amperes without inducing more than 200,000 volts on a phase conductor, assuming there were no ground wires present. The coupling effect of the ground wire reduces the induced voltage still more.

Mr. Hagenguth's criticism of equations 8 and 11 as being inaccurate is incorrect. These equations are a rigorous solution for the assumptions made. They correctly represent the effective charge distribution along the stroke channel at any point along the surface of the earth.

The method of calculation rigorously accounts for the presence of the computed voltages as required for the assumed distribution of charge and current in the stroke channel. The method also includes rigorously the effects of bound charges which seem to bother Mr. Hagenguth.

The authors wish to thank Mr. Golde for his interest in the paper and for the detailed comments which he has given. It is gratifying that two widely separated investigators have come to substantially the same conclusions regarding the general nature of the phenomena. Most of the differences between the points of view regarding the assumptions that the authors use arise from Mr. Golde's application of them to strokes to earthed parts of the transmission system. The limitations of the assumptions used were recognized by the authors. Induced voltages produced by strokes to ground wires and towers, and the preliminary induced voltage preceding a direct stroke were specifically eliminated from consideration. The basis for this action lay in the lack of sufficient fundamental data concerning the nature of rates of rise of currents and the character of upward streamers, factors which have a predominant effect in determining the nature of these voltages.

Mr. Golde is under the impression that the agreement between calculation and statistical data in Figure 33 is only fortuitous, on the assumption that the field data must contain a number of records to ground wires which would vitiate the results. Actually, the data in Figure 33 were obtained on transmission lines which were not equipped with overhead ground wires. They were produced by positive polarity surges which did not cause flashover. The authors recognize that in the case of a stroke to a ground wire the initial portion of the induced stroke on a line conductor will, for a negative stroke, first have a predominantly high positive value, followed rapidly by a surge of negative polarity caused by coupling action.

The authors would like to discuss Mr. Golde's statement that "The tip of the return stroke is still in electric contact with the cloud and therefore, omitting the voltage drop along the leader channel, is practically at the cloud potential of several million volts." The authors picture the phenomenon as one in which the initial leader is a conductor of relatively high impedance, and that the return stroke is a process in which this poorly conducting path is converted into one of higher conductivity. Therefore, it would appear that the potential of the tip of the return streamer would lie somewhere between the actual potential of the cloud and ground, but, because of the higher conductivity of the return stroke, it would be much closer to ground potential than cloud potential.

The basis for the authors' statement that the return stroke velocities increase with current magnitudes is given in the paper in the section under "Velocity of Return Streamer." From a knowledge of the lower and upper range of velocities and similar data for stroke currents and the indications that return-streamer velocities increase with current, the simple assumption was made that these velocities could be segregated in the manner shown according to currents. Mean values were then assigned to each range. This segregation should be sufficiently accurate for the purpose.

In conclusion, the authors believe that, for the subject with which the paper is concerned, namely, the induced voltages produced by strokes to ground in the vicinity of a transmission line, the assumptions and analysis have been sufficiently justified in the paper. The paper does not consider the effect of strokes to the transmission line proper, whether the contact is made to either a conductor or a ground wire. In America, this type of stroke is usually regarded as a direct stroke. Most of the transmission-line design is based upon so locating the ground wires that they adequately shield the current-carrying conductors. Thus it is generally assumed that the stroke strikes a ground wire, and the resulting difference in potential between conductors and tower or ground wire is calculated, taking into consideration such factors as tower footing resistance, coupling factors, and so forth. It was not intended to discuss this type of stroke in the paper.

Practical Design of Counterpoise for Transmission-Line Lightning Protection

Discussion and authors' closure of paper 42-91 by E. Hansson and S. K. Waldorf, presented at the AIEE summer convention, Chicago, Ill., June 22–26, 1942, and published in AIEE TRANSACTIONS, 1942, August section, pages 599–603.

Herbert B. Dwight (Massachusetts Institute of Technology, Cambridge, Mass.): The interesting measurements presented in the paper by E. Hansson and S. K. Waldorf, besides leading to the six general engineering conclusions listed in their summary, provide an unusually good check on ground-resistance formulas, and they show the practicality and desirability of making ground-resistance calculations.

Practical questions described in their paper, such as "What percentage reduction in tower-footing resistance can be expected by putting in one or more additional buried wires?" can be answered easily and reliably by the ground-resistance formulas.

In checking the measurements given in Table II and Figure 1 of the paper, the average resistivity of the ground was first computed from the average of the resist-

$$\frac{1}{C}=\frac{2q\times19.03}{4q\times4{,}800\times2.54}$$

Resistance to ground of two wires 40 feet apart

$$=\frac{178{,}000}{2\pi}\times\frac{19.03}{2\times4{,}800\times2.54}=22.1 \text{ ohms}$$

The measured value, from Figure 1 of the paper, is 22 ohms.

Other cases calculated give curves of the same shape as those in Figure 1, and agreeing with them within 11 per cent or less.

The reduction in ground resistance by putting in a middle wire is shown in Table I of this discussion.

In a similar manner, the data in the last half of Table III of the paper can be computed from the average of the first four items, as shown in Table II of this discussion.

The practical check on the accuracy of the formulas is welcome. But, in future work, when an engineer wishes to know what percentage of change in ground resistance should be caused by a given change in counterpoise design, the information can be obtained more reliably by calculations of the type described than by comparing with previous tests. Such calculations are so short that they could be made in the field as soon as a measurement has shown that a tower-footing resistance is too high.

1. Calculation of Resistances to Ground, H. B. Dwight. AIEE Transactions, volume 55, 1936, December section, pages 1319–28.

L. A. Terven (West Penn Power Company, Pittsburgh, Pa.): The West Penn Power Company has in operation 3–132 kv single-circuit steel-tower lines which are provided with counterpoise, and one of them has been in service long enough to accumulate data to afford a comparison of lightning-protection characteristics with and without counterpoise. The line extends 58.8 miles from Lake Lynn on the border of West Virginia and Pennsylvania to Cumberland, Md., over a mountainous terrain with high-resistance substrata. The construction is horizontal with 20-foot separation between conductors and two ground wires are provided approximately ten feet above the conductor and separated 20 feet from each other. Because of the poor lightning performance of the line it was decided in the fall of 1936 to install continuous counterpoise between towers with unusually high footing resistance (the 17 towers affected averaged 171 ohms footing resistance). At the time six years of lightning season records had shown 15 interruptions. Some 9,000 feet of number 2 copper weld counterpoise was installed about 18 inches under the surface and was connected from tower to tower.

Table III of the discussion shows the lightning performance of the line before and after the counterpoise had been installed. The year 1937 is not considered, because the counterpoise was installed during the lightning season of the year.

Table III. Lightning Performance Before and After Installation of Counterpoise

Year	Interruptions Due to Lightning	Per 100 Miles Per Year	Remarks
1934	2	3.4	
1935	5	8.5	
1936	1	1.7	
1934–36 Average	2.67	4.5	
1937	1	1.7	Counterpoise installed during the year
1938	2	3.4	
1939	1	1.7	Quick reclosing in service from here on
1940	2	3.4	
1941	1	1.7	
1939, 1940	*5	8.5	
1938–41 Average	2.75	4.7	

* Instantaneous tripouts which did not result in interruptions due to quick reclosing.

In the spring of 1939 quick reclosing breakers were installed at the line terminals which served to mask the performance of the line. Five instantaneous reclosures were registered in 1939–40 which were attributed to lightning, but which did not result in interruptions to service.

The table does not show any improvement in lightning protective characteristics caused by the counterpoise, the average interruptions per year per 100 miles being 4.5 before the counterpoise was installed and 4.7 after installation. Possibly the amount of counterpoise was not adequate, as a number of towers tested to 100-ohms footing resistance, which were not included in the counterpoise program, or perhaps the incomplete shielding of the conductors by the ground wires prevented the effect of the counterpoise being noticeable.

J. H. Hagenguth (General Electric Company, Pittsfield, Mass.): The authors give a very comprehensive study of the effectiveness of low ground resistance on the prevention of transmission-line flashovers. They have found by practical experience that the counterpoise is an excellent means of reducing tower-footing resistances to sufficiently low values to prevent flashover of line insulation where ground wires are used for all of the strokes contacting the towers or ground wires of 220-kv lines and in practically all cases of 132-kv and 66-kv lines. In the latter case, however, the tower current limit appears to be of the order of 60,000 amperes even for footing resistances of the order of six ohms. As stated by the authors, there appears some doubt with regard to actual tower currents, inasmuch as it has been found that currents in single legs are not necessarily equal, and further, that considerable percentages of the total tower currents may flow in the tower braces and therefore may not be measured with links installed at the tower legs only. Multiplication factors up to two have been found applicable, depending on the tower structure, to arrive at total tower currents from leg measurements only. In this way the authors calculate a maximum safe current of 120,000 amperes.

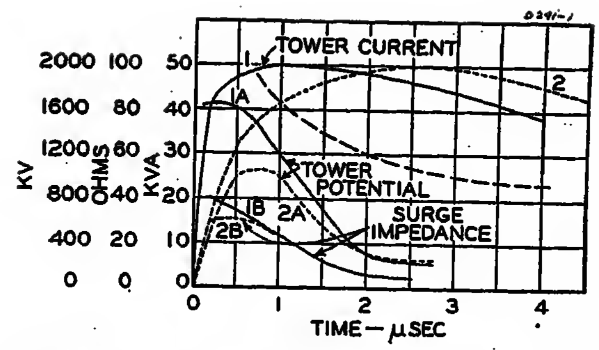

Figure 1. Counterpoise impedance (1B, 2B) and tower potential (1A, 2A) caused by tower currents (1, 2)

D-c resistance of counterpoise—six ohms. Plotted for two 200-foot counterpoises

I believe that our knowledge of the behavior of counterpoises, from theory and tests, is sufficiently accurate to permit calculations of actual voltages at a stricken tower for given current fronts and counterpoises installed. While it is not claimed that such calculations are very accurate, I believe that only by means of such calculations can we finally arrive at the true answer to some of the still unexplained phenomena. More accurate calculations can be made if any particular installation is considered where detailed data of counterpoise resistances are available.

The basis of the calculations is that the counterpoise is a variable impedance as shown by tests.[1] The time variation of this impedance depends principally on the length of the counterpoise and its d-c resistance. The counterpoise impedance varies with applied current wave front[2] as indicated by Figure 1 of this discussion. Multiplication of instantaneous values of current and counterpoise impedance results in the instantaneous tower voltage. The tower current is assumed to have a current peak of varying fronts and a tail of ten microseconds to half value on lines equipped with ground wires. The length of the tail of the tower-current wave depends essentially on the length of the span and the value of ground resistances of the towers. There is some evidence that the current peaks in stricken transmission-line towers are substantially of this order.

Figure 2 shows the crest values of tower voltages thus calculated as functions of tower-current wave front (solid lines) and the expected arc-over voltage of the insulator strings in use on the 66-kv lines described in the paper (635-kv negative 1.5×40 wave). The arc-over voltage curve is cor-

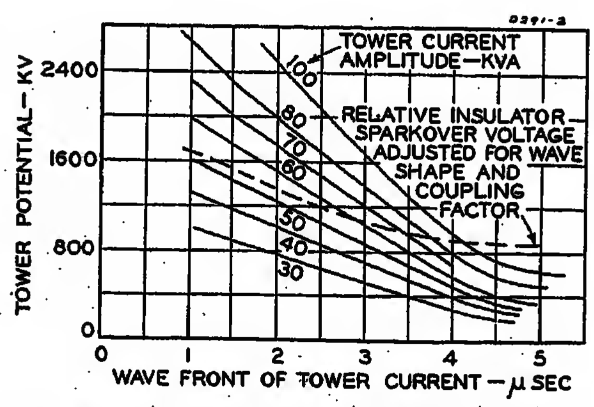

Figure 2. Maximum tower potential as function of wave front and amplitude of tower current for two 200-foot counterpoises connected to tower

D-c resistance of counterpoise—six ohms

rected for the type of voltage wave and the coupling factor given in the paper. Four parallel counterpoises of 200-foot length are used with combined d-c resistance of six ohms. The effective impedance used is the impedance of one counterpoise divided by four. This is not strictly true because of proximity effects between counterpoise wires in the same span, but suffices for the purpose of this example.

Figure 3 of this discussion shows a similar calculation for two 200-foot counterpoise wires with assumed d-c resistance of six ohms. Curves of this type show that the amplitude of the tower current, which will not cause flashover, greatly depends on the current front, as well as on the number of counterpoises installed. The tolerable current for a four-counterpoise ground is of the order of 1.6 times as great as for the two-counterpoise ground, even though the

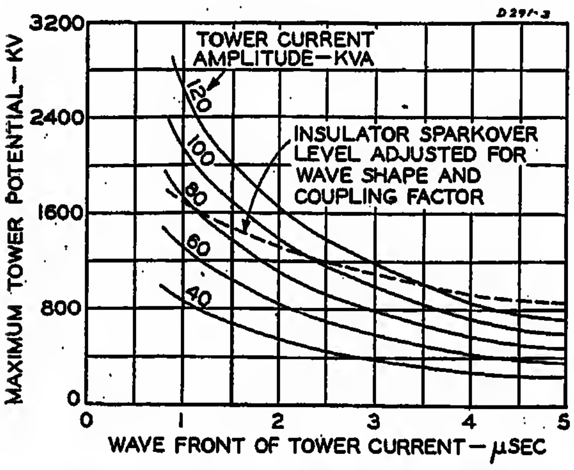

Figure 3. Maximum tower potential as function of wave front and amplitude of tower current for four 200-foot counterpoises connected to tower

D-c resistance of counterpoise—six ohms

d-c resistance of both systems is equal. If, therefore, the tower current causing flashover on a two-counterpoise tower is 60,000 amperes, this would indicate that the current front of the tower current was of the order of not more than three microseconds. On the other hand, if the current was 120,000 amperes, the current front would have to be of the order of not more than 4.5 microseconds. Similarly, on a four-counterpoise tower, 80,000 amperes require a tower-current front of less than one microsecond and 120,000 amperes a front less than 3.5 microseconds. On this basis, a 60,000-ampere tower current should not cause sparkover on a tower grounded through four counterpoises.

It would be interesting if the authors could give in greater detail the conditions existing at towers of the 66-kv and 132-kv lines where sparkover occurred, the number of counterpoises installed and the probable amplitude of the tower current causing the flashover. A comparison of the data obtained in the field with curves of the type shown in Figures 2 and 3, would provide a valuable check between theory, laboratory tests, and actual lightning performance of counterpoise systems.

F. O. Wollaston (Commonwealth Edison Company, Chicago, Ill.): Much of the information in this paper was made available to Commonwealth Edison Company by the authors and their associates for use in designing the counterpoise installation on the 220-kv Powerton–Crawford line. This information proved very helpful in the preliminary layout of our counterpoise system.

In the actual installation of counterpoises, which were of the discontinuous type, no practical means of predetermining counterpoise requirements was found. The procedure actually followed was to install successively wires up to 300 feet long, starting each wire at the tower. The combined resistance of tower footing and counterpoise wire was measured after each 100 feet of wire had been buried, and installation continued until the desired ohmic resistance was obtained.

Footing resistances were measured in all cases by the probe method, employing a Megger-type ground tester, and auxiliary current, and potential probes. While this method is satisfactory for determining the resistance of tower footings and driven grounds, it must be used with considerable care for counterpoise systems; otherwise some uncertainty will always exist as to the true ground resistance. The auxiliary grounds must be located far enough from the ground under test to eliminate errors caused by the large area covered by the grounding system. It will generally be found necessary to investigate the effect of varying the spacings of the auxiliary probes, and to determine the minimum distance at which accurate readings are obtained. For tower lines with extensive counterpoise system, the necessary distance to the current probe may be several hundred feet.

P. L. Bellaschi (Westinghouse Electric and Manufacturing Company, Sharon, Pa.): An important characteristic of grounds is the lowering of the impulse resistance with current. This is particularly the case for grounds driven in high-resistance soil.[1]

Other important factors connected with the problem of grounds are the effect of the discharge-circuit or lead inductance, and the conditions in the earth. Conclusion 1 in the paper by Hansson and Waldorf and the field experience reported previously[2] focus attention on the inductance drop and its importance. The lead or tower inductance becomes particularly significant when steep-front currents of high magnitude are discharged to earth. For example: analysis shows that for a 2x40-microsecond, 40,000-ampere current the voltage developed in a 50-foot down lead or a 100-foot tower may well attain several times the ground-resistance drop (five-ohm resistance ground). This inductance drop is practically over in two microseconds.

Besides the lead or tower inductance, appreciable inductance may be present also in the ground proper, as is the case for grounds driven deep into the earth, or for a counterpoise spread over a wide area. Consider, for instance, a five-ohm 100-foot driven ground or counterpoise which taps its low resistance largely at the further end from the tower. The total inductance of the rod or conductor is in the order of 50 microhenrys, and, accordingly, this ground would have a time constant of about $L/R=50/5=10$ microseconds. A current rising to crest in a time shorter than this, naturally builds up a voltage across the ground which is the sum of the two drops, $L(di/dt)+Ri$. For currents rising rapidly to high crest values, the initial voltage developed across the ground is largely the inductance drop, and this can reach magnitudes considerably greater than the resistance drop corresponding to crest current. If the resistance is distributed along the length of the conductor or rod, the relationship of the two drops is more complex than previously stated—only a part of the total inductance of the conductor or rod is effective.

The foregoing are limiting factors. They do not, however, detract from the fact that deep grounds or counterpoise grounds, as the case and circumstances require, provide an easier path to the current discharge to earth.

1. Impulse and 60-Cycle Characteristics of Driven Grounds—II, P. L. Bellaschi, R. E. Armington, A. E. Snowden. AIEE Transactions, volume 61, 1942, pages 349–63.

2. Experience With Preventive Lightning Protection on Transmission Lines, S. K. Waldorf. AIEE Transactions, volume 60, 1941, June section, pages 249–54.

S. K. Waldorf and E. Hansson: It is not surprising that the performance of the transmission line described by Mr. Tervan was not improved by the addition of the counterpoise. The installation was made along only about three per cent of the line, and apparently the footing resistances of most of the towers in the line exceeded by a good deal the optimum footing resistances recommended in the summary of the paper under discussion. Undoubtedly Mr. Terven's analysis that the amount of counterpoise installed was not adequate is the fundamental reason for the lack of improvement in the line's performance.

It is interesting to note that Mr. Wollaston has also found field measurements as the only practical guide for counterpoise installation. Perhaps there are some localities where counterpoise characteristics can be satisfactorily predetermined, but Mr. Wollaston's experience around Chicago and that reported in the paper indicate that there are at least two widely separated territories where individual field testing of counterpoise is required during installation. Mr. Wollaston's comments on the spacing of auxiliary probes for ground-resistance measurements is welcome confirmation of the experience summarized in the first paragraph of section VI of the paper.

Professor Dwight suggests that the ground resistance of a counterpoise system can be calculated in the field and that the proper amount of conductor can be predetermined for a given location. This can occasionally be done, but field experience in the territory covered by the paper and that cited by Mr. Wollaston show that this is usually impossible. Changes in soil resistivity are frequently so large and abrupt that the resistance of 100 feet of wire is no

sure criterion of the effect of the next 100 feet installed. Usually such changes occur most often when the counterpoise system passes from a wooded section into a cultivated field, or vice versa. A method of designing counterpoise systems was tried in which the required amount of conductor was calculated from the ground resistance of tower foundations, tower-foundation resistances themselves being a measure of soil resistivity. The field results differed so frequently and so widely from those predicted by calculation that the method was abandoned in favor of the cut-and-try or install-and-measure method.

The accompanying Table IV of the discussion complies with Mr. Hagenguth's request for more complete details about towers at which flashovers have occurred and at which counterpoise was installed.

Table IV. Flashovers on Transmission Towers Provided With Counterpoise

Line and Tower	Tower Current in Amperes	Ground Resistance of Counterpoise in Ohms	Tower Potential (I×R)	Type of Counterpoise Installed
Holtwood–York Tower 63 (66 kv)	58,400	13.8	805 kv	Two 1,075-ft conductors west to next tower, two 425-ft conductors east to next tower
Holtwood–York Tower 145 (66 kv)	60,000	19	1,140 kv	Two 500-ft conductors west to next tower, two 425-ft conductors east to next tower
Holtwood–Coatesville Tower 40 (66 kv)	64,400	17.2	1,110 kv	Three 400-ft conductors west, four 600-ft conductors east to next tower
Holtwood–Coatesville Tower 97 (66 kv)	60,200	5.4	325 kv	Two 750-ft conductors west to next tower, three 400-ft conductors east
Safe Harbor–Perryville Tower 15 (132 kv)	52,600	12.2	640 kv	Four 300-ft conductors north, four 825-ft conductors south to next tower

The Holtwood–York 66-kv line with a coupling factor of 0.35 gives an insulating level of about 980 kv. On the Holtwood–Coatesville 66-kv line the corresponding values are about 0.25 and 850 kv, and on the Safe Harbor–Perryville 132-kv line they are about 0.35 and 1,550 kv. The counterpoise systems at the towers of Table IV are all arranged in simple patterns such as shown in Figure 2 of the paper. The tower currents were in every case either the sum of currents measured in the four corner legs of the tower or the current measured in one corner leg multiplied by four.

Mr. Bellaschi's analysis of the behavior of counterpoise and long ground rods helps one to understand the phenomena involved when flashovers occur with low measured ground resistances.

Effect of Lightning on Thin Metal Surfaces

Discussion and authors' closure of paper 42-104 by K. B. McEachron and J. H. Hagenguth, presented at the AIEE summer convention, Chicago, Ill., June 22–26, 1942, and published in AIEE TRANSACTIONS, 1942, August section, pages 559–64.

M. Newman (University of Minnesota, Minneapolis, Minn.): The paper by K. B. McEachron and J. H. Hagenguth presents several very interesting cases of lightning to spheres on top of radio towers, where many of the strokes went to the lower half of the sphere with the top of the sphere apparently shielded to some extent. It would seem that an explanation of this effect could be advanced on the basis of relative gradient distribution about the sphere portion and the supporting shank. Simple approximate gradient calculations indicate that the gradient about a small radius shank could easily exceed the gradient about the much larger radius sphere itself, especially when the opposite electrode, in this case the cloud, is far removed so as to contribute little relative increase of gradient at the top of the sphere. The writer recalls a photograph in a British publication which shows the case of a 60-cycle discharge which took place around the spheres when they were widely separated, and, while no explanation was given with the photograph, it would seem that the considerations submitted by the writer of this discussion of relative gradients about the sphere and support would fit both the 60-cycle case referred to and the case of the long-duration lightning discharges occurring to the lower portions of the sphere.

It would be of interest to have more complete information on the details of the support and whether any pits were visible on the support itself. It would seem probable that many of the streamers would extend from the supporting shank slightly below the shielding zone of the sphere with a possibility of the completed discharge path shifting to the shorter paths to the sphere surface.

McEachron and Hagenguth are to be greatly complimented on presenting in their paper a great deal of new interesting data which lead to new information. It is hoped the new data will be clarified further in this and other discussions. The points in the present discussion are submitted, because they have a bearing on questions of shielding theory and also on the question of whether the discharges necessarily originated from the sphere.

P. L. Bellaschi (Westinghouse Electric and Manufacturing Company, Sharon, Pa.): I agree with the authors that the fusion found on metallic objects hit by lightning is a source of useful information. For instance, initial information of this character from electric conductors provided a valuable guide during the early laboratory research on long-duration low-current components of lightning strokes, so that important developments on protective devices and other electrical apparatus were well under way in 1938.

From the data discussed in a paper on this subject, which I presented to the Institute a year ago (reference 2 of this paper), the mean value of the charge in lightning strokes to electric-power lines, lightning rods, and to other objects near the surface of the earth was estimated to be between 15 and 30 coulombs. The maximum charge observed was 200 coulombs, but there is evidence from the high volume of fusion that this charge might reach 300 coulombs in rare cases. Although the data presented by the authors may differ somewhat from that obtained by the writer in regard to the methods of test and of analysis, it appears to me that the results seem to be in fairly close agreement.

In addition to their basic interest, these investigations are of direct practical value as pointed out by the authors in determining the minimum thickness of metal for containers of flammable or explosive materials. The question has been asked, "What minimum-size conductor can be used on overhead lines that will not be burned in two by lightning?" According to my data for copper, a number 4 conductor should be satisfactory in most cases. A few cases of larger conductors having been sundered by lightning have been reported, but the evidence is not entirely conclusive. In addition to the heating effect of the stroke, consideration must be given to the mechanical forces exerted on the conductor by the action of the high-current component.

The fusion on metals and the various effects associated with the high-current component provide about the only clues that can be found at the scene to assess the nature and severity of the lightning stroke and to reconstruct the probable or true circumstances in a particular case.

K. B. McEachron and J. H. Hagenguth: With regard to Mr. Newman's question concerning pits on the sphere supports, no information is available for the *WSM* sphere. We have recieved another similar sphere from *WLW*, which had been mounted 828 feet above ground for approximately seven years, with a five-inch-long portion of the shank. The sphere had a 14-inch outside diameter and 23-mil thickness of copper. The inside diameter of the shank was $1^{9}/_{16}$ inch and the outside $1^{7}/_{8}$ inch, with a wall thickness of the shank of $^{5}/_{32}$ inch. There are 122 pits on the shank. The distribution of these pits along the shank is of interest, being 28, 41, 36, 14, 3 pits per one-inch band, starting from the sphere. This would indicate that the number of pits at distances of six inches and greater from the sphere should be negligible. While the theory of gradient distribution is attractive, it is very difficult to state whether the shank is hit and the arc travels to the spheres or whether the sphere is hit and the arc moves down the shank. Because the pits on the shank are numerous only close to the sphere, it should be expected that the sphere would shield that portion of the shank and the stroke channel moves down toward the shank.

The distribution of the holes shows a similar concentration in the center belt as for the *WSM* sphere, about 52 per cent of the holes being found in 42 per cent of the

six-inch-wide zone at the equator. Clerk Maxwell shows the lines of force (Figure III, article 120)[1] caused by a charged point in a uniform field. If we use one of the nearer equipotential surfaces as a metallic surface, we obtain practically a sphere. The gradients there would correspond to the location of the hole. The shank, of course, should upset this field. The rapid decrease in pits on the shank away from the sphere, as well as the distribution of pits and holes in the center belt of the sphere, would indicate that the gradients at the sphere are substantially the same with shank as shown by Maxwell without the shank.

There were a total of 695 pits on the sphere and the shank, 27 holes in the upper half, and 29 holes in the lower half. The largest hole indicated 200 coulombs and was located in the lower half. The expectancy curve checks very closely the curve obtained from the *WSM* sphere, 50 per cent of the holes indicating about 20 coulombs.

Information such as obtained by holes burned in metal and fusion of conductors is, of course, only a very rough indication of the total charge involved. The current values and duration cannot be obtained by such methods. Only the oscillograph or other devices which can measure both time and current amplitude can give accurate results. Oscillographic evidence of the long-duration discharges were first obtained in 1937 at the Empire State Building and reported in 1939 by McEachron.[2] Evidence of fusion in the field is valuable, however, because it shows that long-duration discharges exist not only on tall structures such as the Empire State Building but also on distribution circuits, dwellings, and other structures of relatively low elevation above the earth's surface. There is no reason why results of the tests presented in the paper should not check with Bellaschi's findings on fusion of lightning rods. Combination of such data will result in a better quantitative understanding of the long-duration discharges.

Transient Recovery Voltages and Circuit-Breaker Performance

Discussion and author's closure of paper 42-120 by R. C. Van Sickle, presented at the AIEE summer convention, Chicago, Ill., June 22–26, 1942, and published in AIEE TRANSACTIONS, 1942, November section, pages 804–13.

J. A. Elzi (The Commonwealth and Southern Corporation, Jackson, Mich.): Circuit breakers used as switching devices for equipment such as motors, capacitors, line-charging reactors, and synchronous-condenser starting present one of the most difficult application problems, and breaker performance for these applications has frequently not been satisfactory. This is evidenced by excessive contact burning and distress during operation, both of which are an indication of improper co-ordination between rate of transient recovery voltage and the rate of recovery of dielectric strength between the breaker contacts. It frequently happens that these breakers are nonautomatic in their operation or that the short-circuit duty is quite low, so that interrupting rating is not a suitable criterion for the selection of a breaker.

The results of the tests presented in this paper and also the data presented in the companion papers indicate that, even though the rate of transient recovery voltage may be relatively high, it is possible to select a type of circuit-interrupting device which will give trouble-free performance at the relatively low values of current which the breaker is required to interrupt in these applications.

In the past it has been the practice to apply a breaker having a higher interrupting capacity as a remedial measure where such troubles have been encountered. This method has met with some measure of success, but, judging from the results presented in this paper, it appears that a far better approach in making these applications will consist in the proper selection of the type of interrupting device used rather than in simply providing a larger breaker.

F. Von Voigtlander (The Commonwealth and Southern Corporation, Jackson, Mich.): The author shows that the extremes of transient recovery voltages are higher than had been anticipated, but that generally the values actually encountered in practice are much lower. Companion papers have shown that but few circuit breakers have failed in service caused by high transient recovery voltages; yet many circuit breakers now in service were designed before complete data were available on these phenomena.

The writer of this discussion would therefore like to ask whether the present switchgear may not be overdesigned in this respect, possibly at the expense of other desirable characteristics, and whether worthwhile economies or improvements of other features might not be possible by taking into account the lower recovery rates usually experienced, even though such a procedure might require measures to limit extremes in certain special applications.

Raymond C. R. Schulze (Public Service Electric and Gas Company, Newark, N. J.): Published data in the past have indicated that the recovery rate had a definite effect on the interrupting capacity, but there have been no co-ordinated data or series of tests on this problem. This paper by Mr. Van Sickle supplies some much needed information on the subject.

When I was employed by Public Service Electric and Gas Company my first job was to calculate short-circuit currents and to compare circuit-breaker duties with their ratings. I have had a hand in this job ever since. About the time that we appeared to be up-to-date, something was added to the system, or the manufacturer derated his breakers, and we had to start over again. Sometimes there are too many circuit breakers to be rebuilt or replaced for the money available in any one year, and so it becomes necessary to pick out the worst ones. This is done by comparing the short-circuit amperes, the probability of operation, and the experience on the various breakers. The experience consisted of the recovery-voltage rate and certain miscellaneous factors; before the appearance of Mr. Van Sickle's paper, it was felt that, if the time were available, the recovery voltage rates for the various breakers could be calculated, and then this factor could be separated out of the experience. However, this paper seems to indicate that for oil circuit breakers the arcing time is substantially independent of the recovery voltage rate. (This is above some critical value of recovery rate which is relatively too low to be troublesome.) This is indicated by various figures and statements in the paper. If true, this is fine, because if the arcing time is not appreciably affected by the recovery voltage rate, then there should be no real need for calculating this factor. This should save a lot of work.

On page eleven of the paper, the statement is made that "Published data has frequently shown that breakers with self-generated deionizing action have shorter arcing times at high currents than at low currents." We have had some experience to substantiate this statement. One manufacturer tested one breaker, of which we have a number, and which we felt was rated too conservatively. The rating we finally adopted for this one breaker is 140 per cent of its name plate value, although this particular breaker actually withstood up to 280 per cent of its name plate rating. It has been our practice to replace these breakers when the duties exceeded 140 per cent (when some other work was being done on equipment associated with it). In view of the statement in the paper, and the fact that the breaker actually took more than our rating, perhaps we have spent a lot of money unnecessarily.

Another point in Mr. Van Sickle's paper interests me. Various figures concerning oil breakers show that the arcing time is relatively constant with an increase in either short-circuit current or recovery voltage. However, the arcing time in a compressed-air breaker does increase as the recovery voltage rate increases. I am wondering if this might be an argument for continuing to use oil breakers rather than the compressed-air type.

Considering the data which Mr. Van Sickle must have on the varying rates of decay of current at various natural frequencies, and the value of a curve of decrement factor versus natural frequency for use in future recovery voltage calculations, I am wondering if Mr. Van Sickle could develop such a curve for the use of the industry.

David C. Prince: For discussion, see page 1016.

R. L. Webb (Consolidated Edison Company of New York, Inc., New York, N. Y.): All of the papers just presented on the subject

of transient recovery voltages as applied to power switchgear should prove informative and useful to both users and manufacturers of circuit breakers.

The paper giving a "Practical Calculation of Circuit Transient Recovery Voltages" provides a simplified method of calculation that can be used with reasonable accuracy by engineers not expert in this particular field. The method was used by us in assisting with the Association of Edison Illuminating Companies survey, and it was found relatively easy to follow. The data furnished on circuit constants are essential.

The paper on "Transient Recovery-Voltage Characteristics of Electric-Power Systems" shows that recovery rates above 5,000 volts per microseconds may be expected on only a small percentage of all breakers. We do not know yet whether further developments in some breakers may be proved essential for satisfactory performance at recovery rates approximating 10,000 volts per microseconds, but utility engineers can give some thought to means for keeping the recovery rates low.

High recovery rates are usually associated with a circuit of very low capacitance connected between a breaker terminal and a lumped reactance, such as a reactor or a transformer. On one such circuit of our 27-kv system the recovery rate was calculated to be 8,600 volts per microseconds. In experimenting with the calculations we found that this rate could be reduced to less than 5,000 volts per microseconds by connecting a five-foot length of lead-covered cable in series with, or as a stub to, the low capacitance part of the circuit. In this case the cable added about 750 micromicrofarads to the capacitance of the connection. Some such correction might be found for any circuit.

It appears, therefore, that the problem of relieving stresses on switchgear resulting from high recovery voltage rates rests with the user as well as with the manufacturer. The user can lay out his connections initially, in many cases, so as to avoid the type of circuit which inherently gives high recovery rates.

It is encouraging to see the extent to which new testing facilities for high voltage-recovery rates have already been used to check the performance of both oil and air circuit breakers. The paper "Transient Recovery Voltages and Circuit-Breaker Performance" describes laboratory tests at the highest recovery rates used so far in test circuits. The limits reached in voltage-recovery rate seem satisfactorily high for proving breaker performance, in view of the upper values found in the AEIC survey. The tests would be more conclusive, however, if high current at rated voltage could be interrupted with associated high recovery voltages applied to the breaker terminals on the same test.

C. Concordia and **H. A. Peterson** (General Electric Company, Schenectady, N. Y.): These papers on transient recovery voltages present a clear picture of the recovery rates which may be encountered in actual circuits, of methods of calculating them, and of the effect of these recovery voltages on circuit-breaker performance for the simplest form of test circuit. However, a review of actual circuit-breaker performance indicates that factors other than the rate of rise of recovery voltage may, in particular instances, have a greater effect on breaker performance; that is, the rate may be low and yet the interruption difficult.

The conclusion brought to light by several recent analytical studies is that the configuration of circuits containing appreciable amounts of capacitance may make them much more severe than the simple circuit considered as the laboratory test. For example, high reactance grounding[1–3] may reduce the recovery rate and at the same time increase the severity. Again, interruption of line charging current has a very low associated recovery voltage but is known to be a severe duty.[4]

The points above are worthy of emphasis, because they are not merely special cases. Rather, one or more phases of a breaker may be required to interrupt a small current with a slow recovery voltage rate since unbalanced faults are more prevalent than three-phase faults. This small current may be either capacitive in nature (similar to line charging current) or reactive, depending upon the assumed condition, phase-clearing sequence, and system grounding impedance. Consequently the foregoing points are essential factors in the development and in evaluating the performance of any breaker.

A. J. Krupy (Commonwealth Edison Company, Chicago, Ill.): As a general comment upon the three papers relating to the system recovery voltages and their effect on the performance of the circuit breakers, I would like to stress a point which was briefly mentioned in the Adams–St. Clair paper and also give some data on the service experience with the breakers which may be of interest to MacNeill and Van Sickle and to others:

When the voltage-recovery calculations were completed and the results analyzed, it was found that a fairly large percentage of the system breakers were subjected to a high recovery voltage. From this, it would appear that considerable trouble should be experienced with the circuit breakers operating under such voltage-recovery conditions. However, in case of our system, a careful check of the service performance of breakers during the period of some 20 years showed that there was not a single case of breaker failure or even any serious distress which could be definitely traced to a high rate of voltage recovery. Such breaker failures as did occur were invariably confined to the breakers with the previously known inadequate interrupting capacity, or to those which failed because of some other clearly established reasons.

This leads us to the conclusion that a substantial well-designed breaker, which has an ample thermal capacity and a sufficient interrupting duty for a given location, has given us a remarkably satisfactory service even at the locations which in calculations gave rather high recovery voltages.

The above service record may be explained in several ways:

1. The calculations were made for the most pessimistic system conditions which exist only a small fraction of the total service time, and, therefore, the calculated results are unduly pessimistic.

2. A three-phase ungrounded fault, which was assumed in calculations, is a very rare occurrence as compared with the variety of other faults experienced on the system.

3. The breaker itself reduces the voltage-recovery rate to an appreciable extent especially for the high values of current.

4. A breaker which was designed to obtain high interrupting capacity inherently possesses a sufficiently good voltage-recovery characteristic.

5. During the past 20 years, our system has been persistently lucky.

It is most likely, of course, that not only one but several of the above factors were responsible for the observed service record. This does not mean, however, that the work and the tedious calculations which have been made in connection with the survey are of no practical value. On the contrary, in case of our system, for example, it was plainly demonstrated that only a very minor change in the design of a switch house, or a minor change in the connection between the reactor and the breaker, can reduce the initial rate of voltage recovery to a fraction of its original value. Thus, we have found an easy and simple way to control to some extent the voltage-recovery rate at a given location, should conditions arise which would warrant it.

J. B. MacNeill (Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa.): The group of three papers on transient recovery voltages form a symposium covering system conditions and circuit-breaker design aspects. This is a valuable contribution and should correct certain wrong impressions which have grown up over a period of years, and which have been associated with the inadequate performance of early switchgear for difficult restored voltage conditions.

The results of the Association of Edison Illuminating Companies study and the work done by manufacturers in their laboratories, as shown by the Van Sickle paper, may be summarized as follows:

1. Extremely high rates of recovery voltage are rather unusual under normal operating conditions.

2. Modern circuit interrupters are not sensitive to recovery voltage rate as were earlier devices. In fact the average modern interrupter will handle without distress, a broad band of recovery rates.

3. The occasional extremely high-speed rate of recovery does not affect a large system area, and, if necessary, means of slowing down the recovery rate are generally available.

The modern oil circuit breaker fortunately handles widely differing rates of recovery without its performance being affected greatly. This, I believe, is due to the nature of the dielectric in the arc stream during interruption. It cannot be assumed, however, that other forms of interrupter will necessarily have the same latitude in

handling recovery voltages. Radically different forms of interrupter will need to be verified in this important respect. In general, however, laboratory testing equipments present restoration rates higher than average operating conditions. With the knowledge now available on system conditions, design engineers should be able to provide adequately against extended arcing times caused by any reasonable rate of voltage recovery.

R. C. Van Sickle: The discussions of these papers have brought out a number of important points which arise in interpreting the data for circuit-breaker application.

The scope of the data needs emphasis. The tests were made to determine the effect of varying the transient recovery voltage while the current interrupted and the normal frequency recovery voltage were held constant. To obtain the high natural frequencies associated with the most severe transient recovery voltages reactors were placed in the test cells adjacent to the breaker. They limited the current which could be used in this type of testing. These tests fulfilled their purpose by demonstrating the characteristics of the transient recovery voltages which are found with the maximum arcing times. These characteristics were found on the normal testing circuits at the highest currents.

The data demonstrated that at a given voltage and current, increasing the severity of the transient recovery voltage increased the arcing time up to a limit and that further increase in the severity did not further increase the arcing time. This limit was reached well below the values obtained on normal testing circuits.

To fully demonstrate a breaker for a given voltage and current it is necessary to test it with a transient recovery voltage which produces the maximum arcing. A test or service on a circuit which produces less than the maximum arcing can demonstrate the breaker for that service, but the breaker might fail completely if applied on a more severe circuit.

A circuit breaker passing the high-power laboratory test should perform as well or better in service. It does not follow that the breakers are designed with too high a factor of safety for the majority of applications. As shown by the data submitted in this paper, the maximum arcing time of the breakers tested was reached at relatively low natural frequencies of the transient recovery voltage. The voltage-recovery rates corresponding to them can be obtained on over 70 per cent of the breaker locations of the 11,000 to 13,800 volts range as shown by Figure 10 of the paper by St. Clair and Adams. Of the remaining 30 per cent, part will be on circuits which can cause almost the maximum arcing time. A few will be on circuits where they can never be severely stressed. These few might be built less ruggedly but would be hazardous if moved to other circuits requiring the same interrupting capacity but having more severe transient recovery voltages. The few which could safely be applied for light duty only would hardly justify the development and maintenance of a second line of breakers. If other types of breakers are found to have their performance more dependent on the transient recovery voltage, this conclusion might not hold for them.

The data of the survey and the breakers' performances indicate that the majority of the circuit breakers can be subjected in service to conditions which produce their maximum arcing times. The normal testing circuits of the high-power laboratory have fortunately been sufficiently severe to require breaker designs adequate for any service condition.

The arcing time of the compressed-air breakers tested varied less with transient recovery voltage than did the arcing times of the oil breaker. Figure 4 shows that the arcing time of the plain-break oil circuit breaker varied from 0.5 to 3.8 cycles. Figure 9 shows that the arcing time of the de-ion grid breaker varied from 0.3 to 2.1 cycles. Figure 14 for the 1,500,000-kva compressed-air circuit showed no significant difference in the arcing time at 8,000 amperes and an average increase about three-fourths cycle at 36,000 amperes. The cathode-ray oscillograms of the tests at higher current indicated that the maximum arcing time had been reached. As stated in the text, varying the transient recovery voltage rate on the 2,500,000-kva breaker from 300 to 13,000 volts per microsecond at 8,000 amperes 13,200 volts varied the minimum and maximum arcing times by only one or two tenths of a cycle.

The rate of decay of the current in the transients during these tests appears to be approximately proportional to frequency and corresponds closely with the factor used in the survey. Using capacitors for loading the circuit decreased the rate and using transformers for loading the circuit increased the rate, but the variations were relatively unimportant and demonstrated that the factor was satisfactory.

Transient Recovery-Voltage Characteristics of Electric-Power Systems

Discussion and author's closure of paper 42-130 by H. P. St. Clair and J. A. Adams, presented at the AIEE summer convention, Chicago, Ill., June 22–26, 1942, and published in AIEE TRANSACTIONS, 1942, September section, pages 666–9.

W. F. Sims (Commonwealth Edison Company, Chicago, Ill.): As pointed out by Mr. St. Clair in the presentation of his paper, the papers on this subject are based on a survey of voltage-recovery rates on six large utility systems conducted by the committee on electric switching and switchgear, Association of Edison Illuminating Companies. Conditions leading up to this survey should be of interest in consideration of the information contained in these papers.

In 1935 a report on circuit-breaker testing was prepared by the oil circuit-breaker testing subcommittee of the committee on electric switching and switchgear, AEIC, in which it was pointed out that there was insufficient information available in reference to circuit-breaker transient recovery voltage, and it was recommended that a survey be made to obtain this information.

This subject was under consideration by the committee for a considerable time, and in 1939 steps were taken to make the survey, which was assigned to the oil circuit-breaker testing subcommittee under the chairmanship of Philip Sporn. During this period there was considerable discussion with the manufacturers' engineers, and it was brought out that information of this nature was quite important and would be of considerable value in working out of circuit-breaker design.

As a result of these discussions six large member companies of the association, whose properties were representative of both the metropolitan type and long transmission type of systems, agreed to take part in the survey and to make the necessary calculations on their respective systems. The actual work was carried out by a working group of engineers, one from each of these companies, under the direction of H. P. St. Clair. As J. A. Adams had already done considerable work of this kind on the system of the Philadelphia Electric Company, arrangements were made to secure his services in standardizing the methods and coordinating the calculations made on the various systems in order that all work would be done on the same basis and that the data obtained would be comparable. Much valuable assistance was given to the working group by the engineers of the switchgear departments of the large manufacturers.

The results of this survey are described in detail in a report to the committee on electric switching and switchgear presented in the spring of this year. As the information developed appeared to be of considerable importance permission was given to the protective devices committee of the AIEE to arrange for the preparation and presentation of these papers at this session.

David C. Prince (General Electric Company, Schenectady, N. Y.): For many years it has been recognized that the rating of circuit breakers in volts and amperes is not complete. To a considerable extent, the severity of duty is a function of the recovery voltage rate at the point of application. Manufacturers have been handicapped by having to work very largely in the dark, from a recovery rate point of view. That is, circuit breakers had to be designed and built capable of handling the maximum recovery rate which might be encountered, although the designers had no information whatsoever on what that recovery rate might be.

This uncertainty has now been dispelled once and for all by the studies on which St. Clair and Adams are reporting.

Prior to receiving this information, we have speculated with the possibility that low-recovery-rate circuit breakers might be generally applicable with high-duty circuit breakers for only a few isolated cases. The evidence in this paper is that a fairly large fraction of all circuit breakers may be exposed to high recovery rates. In a way, this is disappointing, since it closes the door on the low-duty breaker. On the other hand, from this time on, circuit-breaker designers will know the duty

which their products must meet, and it is only reasonable to expect that with definite knowledge available, ways will be found to tailor the product exactly to the need and in that way reduce the cost to the consumer for a given service rendered.

The data presented by R. C. Van Sickle do not really negate this conclusion. The factors in circuit-breaker design which cause the circuit breaker in operating to alter the rate at which recovery voltage appears involve the dissipation of energy in the circuit breaker itself. In the cases mentioned by Mr. Van Sickle, the kilovolt-amperes interrupted have been small, and the presence or absence of auxiliary losses which altered the recovery rate consequently unimportant. Where higher interrupted capacities are involved, the conclusion might well be different, and it is to be hoped that with the splendid new high-capacity testing station available to him, Mr. Van Sickle will extend his work in that direction.

R. L. Webb: For discussion, see page 1014.

C. Concordia and H. A. Peterson: For discussion, see page 1015.

A. J. Krupy: For discussion, see page 1015.

J. B. MacNeill: For discussion, see page 1015.

J. A. Adams: Mr. Webb and Mr. Krupy mention one of the benefits of the work which has been done on recovery voltages: namely, to suggest to users of circuit breakers that the severity of the recovery voltage characteristics of circuits can be reduced by changes in station design. However, as a word of caution, it should be pointed out that the introduction of lead-covered cable, as mentioned by Mr. Webb, or of capacitors may introduce an additional hazard in some cases. This may be especially true in the case of a switch house where the breakers are located next to the bus with reactors on the line sides of the breakers. If the breakers have been applied on the basis of breaker duties determined for faults beyond the reactors, it is essential that the circuits between the breakers and reactors be made as reliable as possible. Additional capacitance inserted in this portion of the circuit should be obtained in as reliable a manner as possible.

In connection with the Association of Edison Illuminating Companies survey an attempt was made to co-ordinate recovery rates with breaker failures such as was done by Mr. Krupy. This would have given an indication of the effect of recovery rates on breaker operation. However, records in some cases were incomplete, and in others time did not permit the analysis to be made. It is reasonable to expect that in the future this factor will be more carefully studied for its effect on breaker operation.

Mr. Krupy and also Mr. MacNeill point out that actual fault conditions may not result in as severe recovery voltage characteristics as the calculations indicate. This is true, in some cases, because the system connections may not be the same as those for which the calculation was made, and in others, because the fault may not be a three-phase fault or may not be located at the station line terminal. However, the most severe recovery voltage conditions that can be obtained with operating connections should be recognized when applying a breaker. In the survey the calculations were based on connection which gave the most severe characteristics under normal or emergency conditions. In a great many cases these were the connections used for normal operation. Also the calculations were for the highest three-phase fault current that could be obtained for the connections used. In actual practice, the fault might only be phase-to-ground or phase-to-phase and might not be located at the line terminals, both of which factors would tend to reduce the severity of the recovery voltage characteristic.

Mr. Prince refers to the possibility of tailoring breakers to the need and thus reducing costs. It is sincerely hoped that the results of this survey will be of assistance in this respect.

Practical Calculation of Circuit Transient Recovery Voltages

Discussion and authors' closure of paper 42-131 by J. A. Adams, W. F. Skeats, R. C. Van Sickle, and T. G. A. Sillers, presented at the AIEE summer convention, Chicago, Ill., June 22–26, 1942, and published in AIEE TRANSACTIONS, 1942, November section, pages 771–9.

G. W. Dunlap (General Electric Company, Schenectady, N. Y.): In the consideration of transient recovery voltages there are four general methods by which the form of such voltages may be obtained for a given circuit or system. These may be listed as:

1. Direct oscillographic measurement during actual fault interruption.
2. Mathematical analysis.
3. Electrical analysis of miniature circuit representing actual circuit.
4. Electrical analysis by measurements on actual circuit.

All of these methods have their limitations and advantages, and all have been used to obtain valuable information and must be considered as supplemental to each other. The authors have presented in their paper a new and simplified technique for the second method which should greatly increase its usefulness, and it is the purpose of this discussion to point out how the advantages of methods 3 and 4 may be readily made available to supplement calculations by the use of the simple device called the recovery voltage analyzer, which is described in the author's reference 10.

This recovery voltage analyzer may be used on either actual circuits or miniature representations thereof. It performs electrically the same trick of injecting a current into the circuit under study that is used mathematically as the basis for calculation of transient recovery voltages, and, in case of the analyzer, the answer appears on the screen of a cathode-ray tube as a stationary trace of the transient recovery voltage desired. In other words, with the analyzer connected to the circuit for which the curve of Figure 11 was calculated, the Figure 11 curve would appear on the cathode-ray tube to be observed, measured, or recorded photographically as desired.

As pointed out in the paper, it is extremely important that the capacitances associated with higher-frequency circuits be estimated accurately, and in such cases the analyzer may be used to advantage, not only to check calculations based on estimated capacitances with actual measurements of recovery transients, but to measure these capacitances as well. In addition, since the analyzer does not care how complicated a circuit may be, such measurements may be used to check the validity of the simplifying assumptions made for purposes of calculation. The analyzer has been used to make such measurements on a number of power systems. Wherever it is possible to de-energize a circuit for analyzer application the actual measurement is accomplished with such speed and facility that the time of calculation may be saved, and this has also been done in a number of cases.

This feature of speed brings up the possibility of using the analyzer to eliminate the routine work of calculating points on the recovery transient curve. The simplified lumped constant circuit of Figure 10, for example, could be connected to the analyzer, and by the throwing of a switch the recovery transient could be made to appear in its complete form on the cathode-ray tube, and the envelope or any portion of the wave desired could be measured. If there were any doubt as to the validity of estimated capacitances, the values could be varied over any desired range, and the effect on the recovery transient would be immediately apparent.

Still another use of the analyzer is in determining the characteristics of individual circuit elements such as generators, transformers, reactors, and so forth. In this way values of natural frequency, equivalent inductance, and capacitance may readily be obtained for subsequent use in calculation of a system as a whole.

In conclusion, it would appear that the usefulness of the method described by the authors may be further enhanced by including the feature of electrical analysis as embodied in the recovery voltage analyzer.

W. F. Sims: For discussion, see page 1016.

R. D. Evans (Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa.): The authors deserve commendation for the methods of recovery voltage calculation and the data on capacitance that they have presented.

For network problems of the complexity treated in the paper the solutions are not rigorous, and only reasonable engineering accuracy is intended. Bold approximations have been used by the authors to reduce the networks to a more manageable form, for which rigorous and practical solutions are available. These approximations will give good accuracy when skillfully used. Nevertheless, a word of caution is desirable for the benefit of those who are unfamiliar with such calculations but have occasion to use the methods presented in the paper; unless

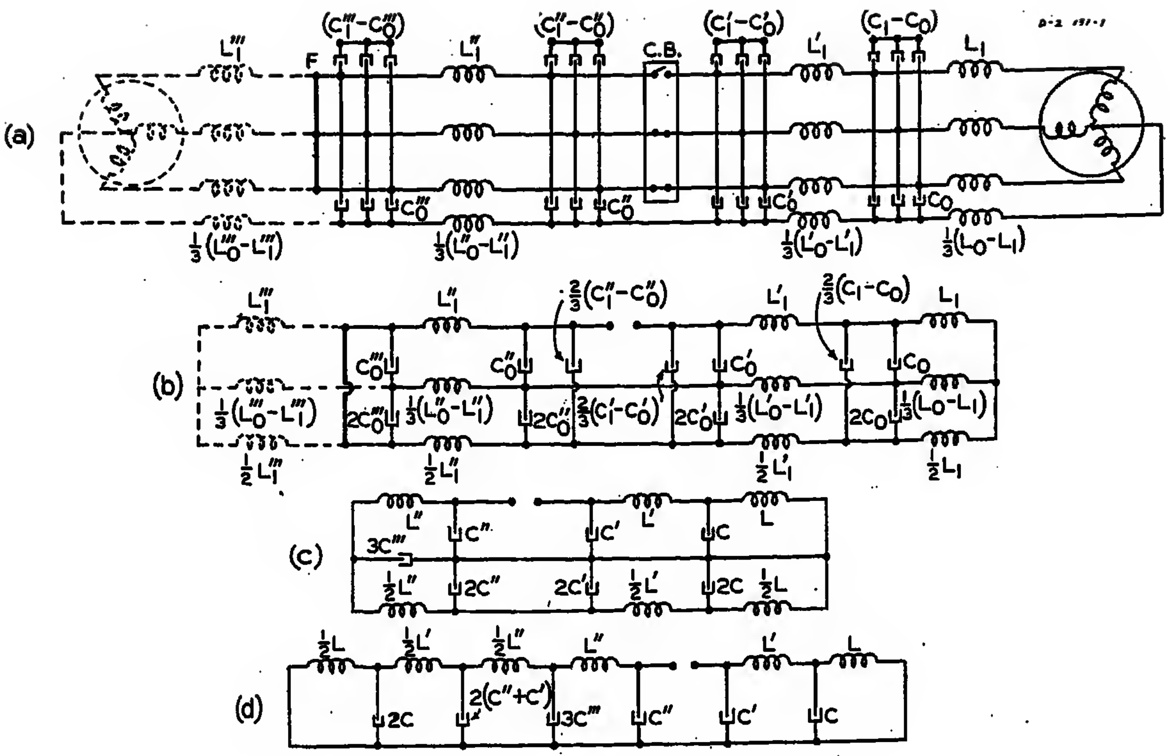

Figure 1. Equivalent circuits for recovery voltage calculations

Symmetrical-component presentation

Network simplifications

the approximations are permissible for the particular case, the accuracy will be considerably reduced.

For setting up the network for recovery voltage calculations, there are several possible methods, including the single-phase method used by the authors. We, however, prefer to start with a netowrk based on symmetrical-component methods, such as described by Evans and Monteith.[1] This is a general method for setting up networks and permits representation of circuit elements which may be unequal for the positive-, negative-, and zero-sequence circuits. This method is convenient because of the practice nowadays of calculating the constants of circuit elements by symmetrical components. The labor of the symmetrical component method is about the same as that of the single-phase method for the cases where the latter is applicable.

One method of using symmetrical components to set up the equivalent circuit for recovery voltage calculation is shown in Figure 1a of this discussion with the inductances and capacitances indicated by the usual notation. This network corresponds to the system of Figures 4 and 5 of the paper but is presented in a more general form which permits differences in the positive- and zero-sequence inductances and capacitances of the various circuit elements. In addition, there is provided a path for zero-sequence current through the feeder beyond the fault, as shown by the dotted line section of the figure. For the opening of the first pole of the circuit breaker for the case of a three-phase ungrounded fault, it is permissible to parallel the two remaining phases which reduces the network of Figure 1a to that of Figure 1b. If it is assumed that the positive- and zero-sequence inductances, and the positive- and zero-sequence capacitances of the various circuit elements are equal, and if the zero-sequence path through the feeder beyond the fault is neglected, the network of Figure 1b reduces to that of Figure 1c, in which the subscripts have been dropped for convenience. By simple rearrangement, the network of Figure 1c reduces to that of Figure 1d.

The network of Figure 1d may be simplified in various ways to reduce it to a more manageable form for calculation. The authors do this by:

1. Reducing the left-hand part to three meshes by combining capacitances $2C$ and $2(C''+C')$ (ignoring the latter) and combining the inductances $^1/_2L$ and $^1/_2L'$.

2. Reducing the right-hand part to one mesh by combining the capacitances C and C' (ignoring the latter) and combining the inductances L' and L.

The procedure just described reduces the network of Figure 1d to the form of Figure 9 of the paper. An alternative method of simplifying the network is to ignore the small capacitances $2(C''+C')$ in comparison with the adjacent large capacitances $2C$ and $3C'''$ and combining the inductances $^1/_2L'$ and $^1/_2L''$. If the inductances in the two right-hand meshes of Figure 1d are relatively large in comparison with the remaining inductances, it would be desirable to use a two-mesh solution for this part of the circuit instead of the single-mesh solution used in the paper.

In setting up equivalent networks for the solution of transient problems, it is preferable to start with accurate network representation for the various circuit elements and then with the network in view to simplify it by the usual methods, such as combining branches in series and in parallel or eliminating unimportant branches. This procedure is preferable to one in which certain branches are eliminated and other branches combined before the network has been set up.

C. Concordia and H. A. Peterson: For discussion, see page 1015.

Raymond C. R. Schulze (Public Service Electric and Gas Company, Newark, N. J.): This paper is very interesting to me, since I was one of those people involved in the recovery voltage rate survey. When the survey was started, the working group was called together, and Mr. Adams outlined the method of calculation. The procedure is clear and easy to follow, except that there appear to be certain disadvantages to the application of Boehne's method for the calculation of the various natural frequencies. This method requires the combination of certain inductances and capacitances in order to reduce the number of oscillating circuits, and then it requires the use of certain very complex graphs which appear as Figures 20 and 21 of the paper.

The objection to the method is based on these thoughts:

1. The combination of certain inductances and capacitances results in a circuit with a natural frequency, which does not actually exist in the system; certain actual frequencies, therefore, do not appear in the calculations. This may result in an erroneous value of recovery voltage, and recovery voltage rate. Also, when combining inductances, one must be careful to maintain the true series circuit of inductances (reactances) from the generators to the fault, in order to maintain the proper voltages across each reactance of the system.

2. The graphs of Figures 20 and 21 are quite complex, and one must have blind faith in the accuracy of the graphs and in the factors which one reads from these graphs.

3. Furthermore, there is no way to check one's work when using this method, except to repeat the whole process (and perhaps the same mistakes).

Therefore, the method used in Public Service Electric and Gas Company was to continue with the diagram of Figure 6 and to resolve it into its oscillating circuits without any reduction in the number of circuits. This meant that there were as many oscillating circuits in the final diagram as there were in the original system diagram. This meant, in turn, that each natural frequency in the system was represented in the calculation. Trouble may be experienced because of a change in the natural frequency of a circuit, when the natural frequencies of two adjoining circuits have a ratio of less than two to one, but in these cases the correct natural frequencies can be obtained either by using Boehne's graphs for these particular cases (of which there were very few) or by computing these natural frequencies by the usual methods employed for coupled circuits. An excellent reference for a study of the behavior of oscillating circuits is the Bureau of Standards circular 74.

The method utilized in Public Service Electric and Gas Company should be especially useful after reading the conclusions shown in Mr. Van Sickle's paper.[1] Mr. Van Sickle shows that the various natural frequencies die out at varying rates, so that a truer calculation should be possible when each frequency is identified.

Also, the calculations seemed to indicate that the highest value of recovery rate was for a fault just beyond a feeder reactor, and this recovery rate was largely dependent on the natural frequency associated with this reactor. On this basis an equation of a half dozen terms was developed, which gave answers to within five per cent of those obtained by the long detailed process for faults just beyond the feeder reactor.

As mentioned before, Mr. Van Sickle's work shows that the various frequencies die out at different rates. This indicates that the one uncertain factor in the method of calculation is the decrement factor to be used for each of the various natural frequencies. The accuracy of the calculation of recovery voltage could be improved, if a graph of natural frequency versus decrement factor could be obtained.

A. J. Krupy: For discussion, see page 1015.

J. A. Adams, W. F. Skeats, R. C. Van Sickle, and T. G. A. Sillers: The analyzer referred to by Mr. Dunlap should prove to be very helpful in analyses of this kind and would have been used more extensively in the Association of Edison Illuminating Companies survey, had it been available. It was used in at least one case to check part of a circuit which had been calculated, and the results were astonishingly close to the calculated values. However, other circuits which are more complex would probably show wider discrepancies, and in these cases the analyzer should be most helpful. It is usually not possible, however, to obtain the complete recovery voltage characteristic with an analyzer, as this would mean isolating a large portion of the power system, which is generally not permissible.

With respect to the accuracy of the procedure, it was pointed out in the paper that the recovery rate for breakers having the same voltage and current rating may vary over a range of almost 100 to 1 and, while quite different performance may be expected in some cases at opposite ends of this range, it is seldom that an important difference in performance will result from a change of even a good many per cent. The accuracy required in these calculations, therefore, is not of a very high order, and it is quite permissible to sacrifice accuracy to simplicity to a considerably greater extent than could be tolerated in many other fields. This has been done in many instances throughout the paper, as it was quite necessary in order to keep the job within the realm of economic possibility.

Mr. Evans' discussion echoes a warning also found in the paper to the effect that caution must be exercised in applying the methods of the paper where a high degree of accuracy is required.

With further reference to Mr. Evans' discussion, it may be pointed out that the phase-sequence circuit reduces at an early stage of simplification to the same thing as the circuit used by the authors, as may be seen by comparing Mr. Evans' Figure 1c with the authors' Figure 6. The high desirability of this simplification where accuracy requirements permit is indicated by the difference in complexity between Mr. Evans' Figure 1c and his Figure 1b.

The authors agree that it is preferable to start with accurate circuit representation and recommend that this be done to the extent compatible with the complexity of the job. A great many of the simplifying steps will depend upon the relative magnitude of the capacitances and inductances involved. This was the case with the steps between Figure 6 and Figure 8 of the paper, which, as Mr. Evans suggests, would not have been sound under different conditions.

No hard and fast rules can be set up for the simplification procedure, and a certain amount of judgment is necessary in deciding just what steps to take. This is illustrated by Mr. Schulze's discussion which points out that he made rather wide departures. It is probable that the inclusion of all circuits resulted in improved accuracy in some cases, while his distrust of the curves caused some loss in others.

The factors mentioned by Concordia and Peterson should of course be recognized in applying and designing circuit breakers. This paper covers only the recovery voltage part of the picture and makes no attempt to review these other factors.

A Compressed-Air Operating Mechanism for Oil Circuit Breakers

Discussion and author's closure of paper 42-114 by R. C. Cunningham and A. W. Hill, presented at the AIEE summer convention, Chicago, Ill., June 22–26, 1942, and published in AIEE TRANSACTIONS, 1942, September section, pages 695–8.

H. E. Strang (General Electric Company, Philadelphia, Pa.): Development during the last few years on air-blast circuit breakers, in which contact movement is provided by pneumatic mechanisms, has built up a better understanding of the simplicity, sturdiness, and reliability of this type of operating power. It is quite natural that this has led to the development of such air mechanisms for the operation of oil breakers. Similar to others which have been described, the mechanism disclosed by Cunningham and Hill undoubtedly possesses many of these desirable characteristics.

Without belittling in any way the importance of this new type of operating mechanism, it must not be inferred that it alone made it possible to provide the industry with super-speed reclosing circuit breakers. The first mechanisms for such service, which were of the motor-operated type, were installed on 138-kv breakers in 1936 and have been in regular service ever since. Subsequently, over 50 more of this motor-driven cam type have been placed in service, and, as shown by reports to the Institute, have contributed their share in demonstrating the value of this kind of triple-pole, super-speed reclosing service on high-voltage lines.

Since super-speed reclosing of triple-pole high-voltage breakers was already an established procedure, it was only natural that pneumatic operators should be employed for this service. It has now been established that they perform this same function with ease and with the obvious advantages incident to stored energy and low battery drain. Starting with the first installation during the summer of 1940, well over 100 pneumatic mechanisms have already been placed in service on both new and modernized oil circuit breakers of all voltages from 34.5 kv to 230 kv.

In attempting to reconcile the relatively flat output characteristics of the simple air piston with the rising characteristics of force required to close a circuit breaker, Cunningham and Hill have resorted to a mechanically operated throttling valve which opens near midstroke to give the piston an additional boost. Under ideal conditions this should work satisfactorily, but at best it is another moving part which may require some adjustment, maintenance, and attention. A simple toggle built right into the mechanism between the driving piston and the output crank has been found by experience to serve as the means of matching these characteristics, and eliminates the need for throttling valves or other such critical moving parts.

H. W. Haberl (Montreal Light, Heat, and Power Co. Consolidated, Montreal, Que., Canada): If the control mechanism for oil circuit breakers as described in the above paper is to be used in freezing temperatures where large variations above and below freezing occur, it is suggested:

(*a*). That the inlet air to the compressor be passed over by some type of drying equipment; this could be in the form of a glass bottle in which colored activated alumina or silica gel were used as the dehydrated medium; in this way, the air in the storage tank would be reasonably dry.

(*b*). The mechanism's housing be lined with an insulating material, similar to (ten-test) and a thermostat and heater mounted inside the control cabinet which would maintain the control cabinet at or above freezing temperature.

The preceding suggestions would insure the air being free of moisture and consequently would prevent any of the small valves from freezing.

R. C. Cunningham and A. W. Hill: Mr. Strang has pointed out the relative effect of a throttle valve and a toggle, either of which modifies the flat characteristic of the simple air cylinder to match the typical breaker load. One reason for including a simple mechanically operated throttle valve is to make possible the application of this mechanism to existing breakers. In this way, the pull curve is made to follow closely that of the solenoid formerly used.

Another and more important reason for using the throttle valve with a slotted link is to provide controlled flow of air on ordinary closing, and full air flow when needed for rapid reclosure. A range of adjustment, both as to time of operation and amount of opening of the throttle valve, makes it suitable for use on any of several sizes of breaker.

It is obvious also that with the breaker starting from the full open-contact position, air is admitted above the piston when the cylinder volume is smallest, and full air

pressure immediately acts to start movement. A restriction in the air line is permissible and desirable to prevent excessive speed later in the closing stroke. However, for fast reclosure, air is admitted while the piston is part way out in its stroke, so that the full effect of the supply pressure is not felt until after a time interval while air is being poured into this large cylinder volume. A large opening in the air line serves to gain time, so that the utmost over-all reclosing time can be secured.

The use of a drying agent, as suggested by Mr. Haberl, was considered in the early design stages but not adopted, as it would introduce another item requiring maintenance and possibly be the cause of trouble if essential to proper operation and not properly cared for. During freezing temperatures, there is so little water in the air supplied to the compressor that none will be deposited after the air passes the inlet valve. Heaters are supplied to maintain all parts within the housing at a temperature enough above the outside ambient to prevent trouble, although in extreme low outside temperatures it is not considered necessary to keep the parts above the freezing point.

In a test set up at the factory one of these mechanisms was operated at temperatures down to −20 degrees Fahrenheit. Even when air was drawn from outside the cold room, at a temperature of 50 to 60 degrees Fahrenheit, freezing of condensed moisture gave no trouble at any of the control valves. Similar performance is indicated by breakers in regular winter service.

Tests and Analysis of Circuit-Breaker Performance When Switching Large Capacitor Banks

Discussion and authors' closure of paper 42-119 by T. W. Schroeder, E. W. Boehne, and J. W. Butler, presented at the AIEE summer convention, Chicago, Ill., June 22–26, 1942, and published in AIEE TRANSACTIONS, 1942, November section, pages 821–31.

R. M. Partington and **M. E. Scoville** (General Electric Company, Pittsfield, Mass.): The physical arrangement of a capacitor bank and circuit connections determines the inductance and, therefore, affects the magnitude of inrush currents with energizing the bank. Maximum inrush currents are obtained with switching equipments in compact physical arrangements. It may be of interest to compare the inrush currents calculated from physical dimensions to the results of the actual tests made by the authors. Figure 1 shows a compact equipment rated 2,520 kva. A number of such equipments may be grouped together with space to allow for ventilation and accessibility to form a larger bank. One or more of those equipments may be connected to the system through a suitable circuit breaker.

Assuming a typical arrangement for each of the three-phase kilovolt-ampere ratings, wye-connected, inductance and resistance values have been calculated, conservatively leaning toward the minimum practical values. The circuit used for calculation includes individual capacitor units, fuses, bus connections, cable between equipments, and connections up to line side of circuit breakers. The inrush currents were calculated from the relation

$$i\ (\text{maximum}) = \frac{\text{line volts} \times 1.41}{1.73} \times \sqrt{\frac{C}{L}}$$

neglecting resistance which has a negligible effect on the inrush current magnitude.

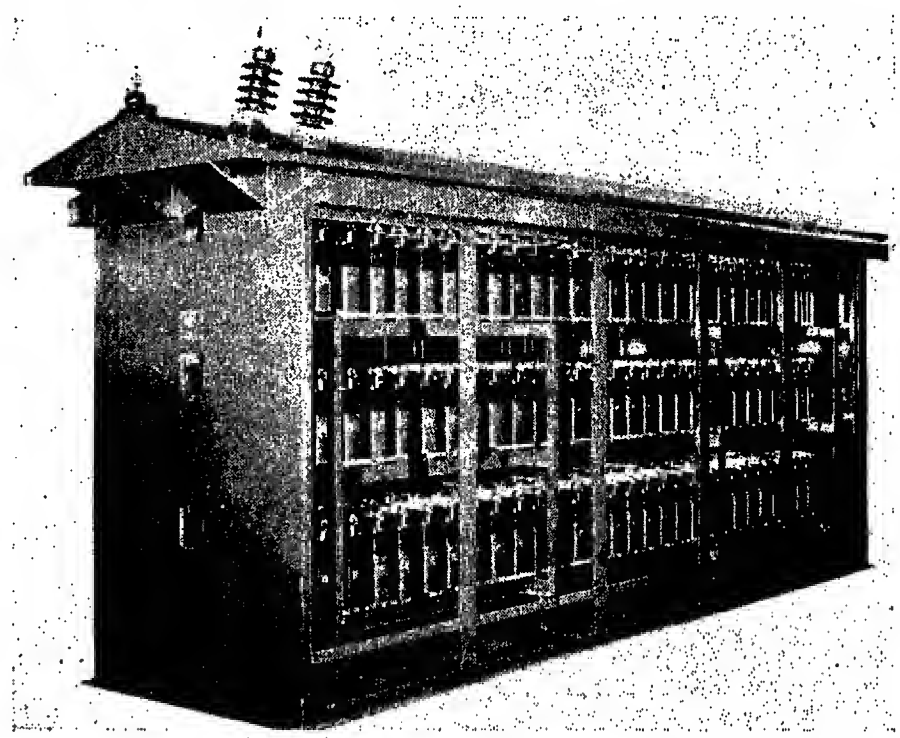

Figure 1. Outdoor large rack-type capacitor equipment, rated 2,520 kva, 13,800 volts, wye-ungrounded neutral, three-phase, 60 cycles

The inrush currents shown in the table are maximum with assumption of infinite bus at line side of circuit breaker terminals. Consequently the presence of other capacitor banks on the same infinite bus would not increase the values of maximum inrush current. Rarely, however, would these inrush currents be obtained in practice since there would be some system inductance ahead of the circuit breaker which would reduce the inrush current?

Table I

Rated 60-Cycle 3-Phase Line		Calculated Values Per Phase			Maximum Inrush Current (Amperes)
Kva	Voltage	Inductance (Microhenrys)	Capacitance (Microfarads)	Resistance (Ohms)	
2,520	4,160	8.17	387	0.0025	23,400
5,040	4,160	4.08	774	0.0012	46,700
10,080	4,160	3.05	1,548	0.0006	76,500
2,520	13,800	9.15	35.2	0.0046	22,100
5,040	13,800	4.46	70.4	0.0023	44,300
10,080	13,800	3.34	140.8	0.0012	73,000
5,400	25,000	11.27	23.0	0.0042	29,100
10,800	25,000	8.45	46.0	0.0022	47,600

Using the inductance and resistance values from the table, it can be shown that the transient inrush current will decrease to a negligible value in less than one cycle (60-cycle frequency). For example, consider the 10,080-kva bank on a 13,800-volt 60-cycle line. The transient current will decrease to one-half its maximum value in approximately one-quarter cycle (0.00416 second), or to one-tenth its maximum value in approximately three-fourths cycle (0.0125 second). The natural period of the transient would be approximately 7,300 cycles per second.

The above calculated data indicate maximum inrush currents of 76,500 peak amperes with a physical arrangement typical of a practical permanent installation except that an infinite bus is assumed at the circuit-breaker terminals. Actually, the additional inductance in 30 feet of line between the circuit-breaker terminals and an infinite bus, which is typical of a practical installation, will limit the peak currents to less than the values obtained in the tests recorded in the paper.

R. D. Evans (Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa.): The transient-recovery-voltage problem for de-energizing capacitors is similar to that which arises from de-energizing transmission lines. The latter problem was investigated several years ago in the paper, "Power-System Transients Caused by Switching and Faults" by Evans, Monteith, and Witzke.[1] It is pertinent to compare the results of these two studies since part of the analytical and transient-calculator work of the present paper follows closely the procedure used in the earlier paper. In that paper a power system with typical sending and receiving stations, and with two 100-mile transmission lines were used for the study of several types of switching transients. The case considered included the de-energizing of one line starting with one and two lines in service. The comparison of the recovery voltages obtained is given in the accompanying Table II.

The difference in voltage transients incident to de-energizing transmission lines between switching lines and de-energizing capacitors depends to some extent on the

differences between lumped and distributed capacitances and the presence of line resistance. However, the more significant difference for many conditions of operation arises from the difference in the positive- and zero-sequence constants. Capacitor connections may be made so as to give widely different ratios of zero- to positive-sequence constants, whereas with transmission lines the ratio is fixed and for the case covered by the earlier paper was in the ratio of 1 to 1.35. This means that the voltage transients on grounded capacitors with neutrals grounded or interconnected should correspond approximately with the transients of switching lines connected to grounded systems.

It is believed that the differences in the results of tests for the comparable conditions from the two papers may be explained on the differences in the circuit constants.

Table II

Switching Conditions	Transient Voltages for De-energizing Operations Expressed as Ratio to Rms Voltage Line to Ground: Voltage to Ground		Switch Volts	
	Transmission Line*	Capacitor**	Transmission Line*	Capacitor**
Grounded neutral				
Transmission line				
Initially 1	2.7		3.6	
Initially 2	2.3		3.4	
Capacitor				
0.5 microfarad		3.0		4.0
0.5 microfarad with 0.2 microfarad unswitched		2.4		4.8
Interconnected capacitor neutral				
0.5 microfarad with 0.2 microfarad unswitched		3.3		4.3
Ungrounded neutral				
Transmission line				
Initially 2	2.6		5.0	
Initially 1	2.2		3.8	
Capacitor				
0.5 microfarad		6.0		6.6
0.5 microfarad with 0.2 microfarad unswitched		6.0		8.2

* Reference 1.

** From the authors' paper.

The earlier paper also gave data on voltage transients for two restrikes. Incidentally, it may be observed that these tests showed lower transient voltages for some value of neutral impedance than with solidly grounded systems.

The results obtained by the authors of the present paper are of interest and show the desirability of reducing transient voltages by grounding capacitor neutrals or by interconnecting them. There is also some advantage in switching capacitors in relatively small blocks.

T. W. Schroeder, E. W. Boehne, and J. W. Butler: Partington and Scoville have provided some very useful data for estimating inrush currents and their duration for typical large banks. It should be emphasized that the inrush or discharge currents will be reduced measurably by comparatively short lengths of conductor to the capacitor banks. It is felt that the maximum test value of 52,000 amperes is sufficient for most practical installations because

1. This is a greater equalizing current than that which will flow between two groups of two 10,080-kva 13.8-kv banks each, with an inductance of five microhenries between the groups. This value is about 44,600 amperes.

2. A bank of 10,080 kva which is shown to have higher inrush current than values reached in test (76,500 amperes maximum) could discharge such current through a breaker only in the case of a solid three-phase fault immediately on the line side of the breaker, which would be a rarity.

3. On energizing such a bank, very small values of system inductance will greatly reduce the possible inrush current.

120-Kv Compression-Type Cable

(42-133)

120-Kv High-Pressure Gas-Filled Cable

(42-135)

Low-, Medium-, and High-Pressure Gas-Filled Cable

(42-102)

Discussion and authors' closures of papers 42-133 and 42-135 by I. T. Faucett, L. I. Komives, H. W. Collins, and R. W. Atkinson, and paper 42-102 by G. B. Shanklin, presented at the AIEE summer convention, Chicago, Ill., June 22–26, 1942, and published in AIEE TRANSACTIONS, 1942, September section, pages 652–7, 658–65, and October section, pages 719–26.

L. L. Phillips (General Electric Company, Pittsfield, Mass.): Some of the all-gas-filled terminals to which Mr. Shanklin refers now are in service at 15 kv. Similarly designed terminals for ratings 23 kv, 34.5 kv, and 46 kv, have been developed and are available for gas-filled cable installations pending. These gas-filled terminals utilize an ingenious method for controlling the electric stresses in the insulation at the termination of the cable-shield extension. The ordinary construction of termination regularly used in compound-filled and oil-filled terminals is unsatisfactory for gas-filled assemblies, because of the differences of voltage distribution resulting from the use of gas as a part of the dielectric.

Stress control is accomplished largely by a specially developed cloth having the capacity to divert a part of the charging current which tends to flow directly to the end of the cable-shield extension. The cloth is processed to have a controlled resistance to the flow of current. It is assembled in contact with the metal of the cable-shield extension to provide a partially conducting cylinder for approximately one inch beyond. The special cloth serves to distribute the charging current through a larger cross section of the insulation, thus preventing concentration at the immediate end of the cable-shield extension. Therefore, a part of the charging current flows from the terminal conductor through the insulation to the cylindrical surface formed by the applied cloth and thence to the cable-shield extension.

In addition to the "shielded" extension for stress control, wrappings of varnished cambric tape are applied to exclude filler gas—except in the thin films between tapes—from regions immediately surrounding the cylinder of special cloth. The total thickness of this applied tape varies according to the circuit voltage at which terminals will operate in service. Thus, any appreciable thickness of the filler gas is prevented from entering the dielectric circuit, except at suitable locations.

L. I. Komives (The Detroit Edison Company, Detroit, Mich.): After seeing with his own eyes 29 inches of vacuum in an impregnated-paper cable line which operated at 24 kv successfully for the last 12 years in Detroit, the writer appreciates Mr. Shanklin's contribution to the industry more than ever before. If some means could be found which would enable the cable user to maintain positive (above atmospheric) pressure at all times in a solid-type cable, certainly more efficient operation could be expected than from the above described Detroit cable. As the service record of the solid-type cable is very good, the insulation thickness may be reduced, or the normal maximum operating temperature (cable loading) may be increased. This is essentially what the low-gas-pressure cable accomplished in addition to the "self-supervision," a feature which is very valuable to the operating engineer.

In this paper Mr. Shanklin takes the apparently very logical step and tries to extend the usefulness of this principle into higher brackets, in regards to both pressure and voltage. He divides the field into three pressure classes and prescribes cables suited for each class. The writer will discuss each class separately.

1. Low-Pressure Gas-Filled Cable

There is only one observation which the writer would like to make with regard to this cable. Nowhere in this nor in Mr. Shanklin's previous AIEE paper describing

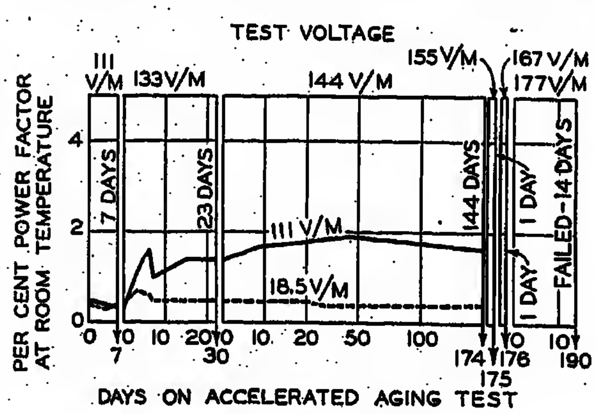

Figure 1

this cable has a direct parallel been drawn nor comparative test results shown which would indicate the superiority of the low-gas-pressure cable over that of an ordinary solid cable. It would be desirable to show for instance paralleling cases for Figures 6, 10, 11, and 12 of Mr. Shanklin's paper where no nitrogen is applied to ordinary solid cables employing the same dimensions and construction as the low-gas-pressure cables shown in Figure 1 of this discussion.

The argument that the low-gas-pressure cable of Figure 6 stood up for more than a year under certain conditions would be more convincing if parallel cases on solid-type cables would be shown. In Detroit solid-type cables stood tests at higher voltages than that shown on Figure 6. One such example is shown on Figure 1 of this discussion.

2. Medium-Pressure Gas-Filled Cable

The economic voltage range for this cable is given as from 40 kv to 69 kv. This is the range which is the most awkward and bothersome from the cable designers' point of view—apparently too high for solid-type insulation and too low to permit the application of reservoirs or other accessories economically. If the medium-pressure system will solve some of the problems in this field, it will be a real contribution. In the opinion of the writer the problem of the high-creep-strength alloy sheath will have to be worked out more completely especially with regard to higher temperatures, resistance to corrosion, and aging. The double-reinforced sheath could be justified in very few cases and under a constant pressure of 30 pounds per square inch. This construction still has to prove itself.

3. High-Pressure Gas-Filled Cable

In paragraph 2 of this discussion the statement was made to the effect that Mr. Shanklin took the "apparently" logical step of extending the gas-feeding principle into the higher-voltage field. As long as Mr. Shanklin tries to improve the solid-type cable, he will find the majority of the cable engineers behind him, because most of them realize the inherent weaknesses. In the higher-voltage field, however, there are several excellent solutions, and naturally these systems should be used as a yardstick when judging Mr. Shanklin's high-pressure cable.

A. Sheaths intact:

1. Compression versus high-pressure: Theoretically the lead sheath is not flexed in the high-pressure system, but it is flexed in the compression system. On the other hand the gas in the pressure chamber is in contact with the insulation in the high-pressure cable from the very beginning, while in the compression system the same conditions will appear only if and when the lead sheath ceases to function as an impervious membrane. Otherwise, the two systems are alike except that the cable of the high-pressure system will cost somewhat more if three-conductor cable can be used, and a great deal more if single-conductor construction has to be resorted to.

2. Oil-filled versus high-pressure: The writer would like to see a comparison in cost between these two types of cable. As the spread between oil-filled and compression cables is not too great, the higher cable cost of the high-pressure system would probably bring it quite close to the cost of the oil-filled system. In such a case the new construction would have to compete with the reliable proved oil-filled system on purely technical basis.

B. Sheaths stripped off:

1. Modified Beaver (*SMD*) versus high-pressure: When Mr. Shanklin strips his sheath, his cable in time becomes an *SMD* cable with the following exceptions:

(*a*). He does not design his cable for such conditions, that is, grades his butt space thicknesses, insures gas supply to all voids, and so forth.

(*b*). He has to use an impregnating compound of lower melting point; otherwise he cannot impregnate. With lower melting point oil drains at corresponding temperatures, and in a large steel pipe there is nothing to hold the oil in the cable insulation. In an *SMD* cable impregnating compound with a much higher melting point may be used.

(*c*). He does not even use strand shielding, because tests on "new" cables do not show the need of it.

(*d*). His cable cost probably somewhat less, because he does not use preimpregnated tape in a low-humidity room. Although in order to obtain good taping, he probably "regulates" the humidity of the taping room.

Between the two alternatives the writer prefers the *SMD*.

Strand Shielding

Although strand shielding did not appear to show any improvement in the long-time tests, it should still be retained, because it influences impulse strength. It is a well-known fact that insulation thicknesses of voltage cables are based on transient voltage requirements. This is emphasized in Mr. Shanklin's paper.

Impulse Tests

The writer would like to add a note of warning to Mr. Shanklin's conclusions. It has been fairly well established that aging does not affect the impulse strength of an oil-filled cable, but it does affect that of the solid-type cable. As the gas-pressure cable constructionally speaking is somewhere between the two, it seems that 21 days aging at 75 degrees centigrade should not be accepted as a complete proof that aging does not affect the impulse strength of the gas-pressure cable.

L. F. Hickernell (Anaconda Wire and Cable Company, Hastings-on-Hudson, N. Y.): Referring to Figure 6 of Mr. Shanklin's paper, it is noted that after 252 days at 85 volts per mil the power factor at 85 degrees centigrade was two per cent. Reference to a published AIEE paper ("The Type-*CB* Impregnated-Paper Cable," by S. J. Rosch, Figure 12), will show that after a similar period at 100 volts per mil, the power factor of type-*CB* cable at 80 degrees centigrade was of the same order (that is, two per cent). From this point on the test conditions are not comparable. Accordingly, from a power-factor-stability standpoint, it would not appear that the added complication of gas-pressure operation were warranted.

Referring to "Strand Shielding," comparison of Figure 6 with Figure 10, insofar as it goes, substantiates the author's conclusion that no great benefit was obtained from stand shielding. Figure 10, however, at the time of writing the paper was incomplete, the cable having been subjected only to the 85-volts per-mil cycles. Since the cable on test was constructed with metallized-paper strand shielding, we presume the author intends to limit his conclusions to this design only.

In reference to "Impulse Tests," it is stated that for all practical purposes, solid, oil-filled, and gas-filled cable have the same impulse strength; this appears reasonable. However, in this connection, consideration should be given to the fact that other investigators have found strand shielding to improve the impulse strength ("Impulse Strength as a Measure of Cable Quality," by L. I. Komives,[2] and "Impulse Strength of 24-Kv Type-*H* Cable," by G. B. McCabe, transmission and distribution committee, Edison Electric Institute, Detroit, Mich., February 17, 1941).

The type *SMD* cable discussed in paper 42-135 is typically American in that it represents a melting pot of ideas. Taking the graduated gas spaces of Beaver, the designers have put the cable in Hochstadter's steel pipe, thrown away the lead-sheath diaphragm, and applied the pressure in direct contact with the impregnated insulation as suggested by Fisher, Atkinson, Bennett, and probably others.

All that is needed to make this a truly up-to-date design would be to incorporate Rosch's carbon-black protection. On this point, however, the designers have apparently been content on simple conductor shielding. Since impulse strength was evidently of some concern (refer to "Impulse Tests"), this seems unfortunate, in view of one of the authors' own data[2] and that of one of his associates ("Impulse Strength of 24-Kv Type-*H* Cable," by G. B. McCabe). These data indicate the highest impulse strength was obtained with type-*CB* construction.

Referring to "Field Tests," in discussing Figure 2, the authors state: "These measurements show no evidence of deterioration of the insulation." So far as it goes, this statement is correct, but it might be added that the data do not show anything else either; certainly not that no deterioration took place. Power-factor measurements at (or below) *room* temperature are valueless as criteria of insulation deterioration. Reference to cyclic-aging data will disclose that during the cycles prior to instability the cold power factor seldom exceeds appreciably the initial power factor. On the other hand, the hot power factor gradually increases until failure (reference 1, Figure 12). It is the high-temperature, not room-temperature, power factor which discloses the presence of deleterious products which cause insulation deterioration.

Referring to "Compound Migration," if a 65-day test at 100 degrees centigrade can be relied upon to indicate the expected life of the cable at rated operating temperature, it would appear that the migration problem has been solved by the use of a high-viscosity impregnant (3,000 Saybolt Universal seconds at 100 degrees centigrade). On the other hand, operating experience on this same system has indicated that viscosity is not the only factor involved in migration. ("Examination of 60 Paper-Lead Cables After Operating in High Vertical Runs," by F. Farmer, underground systems committee, National Electric Light Association,

Detroit, Mich., April 4–5, 1933). It will, accordingly, be interesting to learn at a later date the actual field experience with respect to compound migration. Until such time it might be well to accept summary 3, and possibly 4, with some qualifications. This observation is further prompted by the fact that tests in several laboratories and operating experience have indicated that migration will *eventually* take place, no matter how high the viscosity, if the impregnant is operated above its melt point.

I like one important feature of this system, modestly omitted by the authors, namely, that it has a second line of defense. It it doesn't work with gas, it can always be filled with oil; provided rationing has not extended to the Midwest by that time!

Robert J. Wiseman (The Okonite-Callender Cable Company, Inc., Passaic, N. J.): I am not able to go along with Mr. Shanklin's statement that a pipe cable system is limited in open ground and not adaptable to paved city streets. I think the Detroit Edison installation of the 120-kv gas-pressure cable proves this, and calculations that we have made on installation costs indicate that our Oilostatic cable system can compete very nicely with a cable system drawn into ducts. It is true that it is necessary to draw the three cables into one pipe and, therefore, the heat is concentrated more than for a duct system, but the heat-dissipating properties of a buried cable or pipe are better than a duct, and, therefore, we arrive at the same conductor size or in some cases a smaller size. A steel-pipe cable system (Oilostatic and gas-pressure) is able to carry as heavy loads as is considered good engineering in concentrating in one circuit large amounts of power. The Oilostatic system has a very high emergency-overload characteristic because of the high heat storage capacity of the oil in the pipe and the surrounding earth, so that, if occasion arises, it can be heavily overloaded for several hours without reaching excessive temperatures, and it will cool rapidly when the load is reduced.

I do not agree with the statement in paragraph *d* referring to the effect of exposure of the unleaded cable as it is being drawn into the pipe to absorption of air and moisture, as it pertains to the Oilostatic system, and I also question it for the gas-pressure system. This is another of the fears that we had in the past that is not borne out by facts. We have drawn the individual unleaded cables for the Oilostatic system into pipes for lengths of 1,500 to 4,000 feet, and power-factor measurements did not show any increase. Many of us have stripped lead sheaths off cables, left them exposed, and then measured the power factor without finding an increase over the values before removing the lead sheath.

I am disappointed that the authors of paper 42-133 have not included in the paper any data regarding the thermal characteristics of the compression-cable system. They refer to load-cycle tests that have been made but do not tell us what temperatures were found for the conductor, lead sheath, and pipe, nor show curves of the temperature rise with time when the load is on, and the rate of cooling when the load is off. A load cycle of 2.5 hours on and off and four hours on and off is a very short cycle, and I doubt that the cable arrived at its maximum temperature at all. The 190-hour load cycle should show good data. The heat-storage capacity of a buried-cable system is very large and results in a slow rate of rise of temperature. In the case of the compression cable you have copper, insulation, lead, gas, steel pipe, and surrounding earth. For the high-gas-pressure cable there is no lead. For the Oilostatic-cable system we have copper, insulation, oil, pipe, and surrounding earth. Tests which we have had made on Oilostatic cable indicate the heat capacity inside the pipe is very high and results in a slow rate of rise in temperature outside the pipe. One test indicated that the temperature of the earth 17 inches from the center of the pipe did not begin to rise until six hours after the load was applied to the cable. I would expect the compression cable to have good but not as much heat capacity because of the use of gas which has a very low heat capacity instead of oil surrounding the cables inside the pipe.

I am also interested in the thermal constants for the compression cable, insulation, gas zone, earth. What formulas are used for calculating the thermal gradient in each zone?

The *SMD*-type cable is a logical development from the Beaver-type cable as used in England and the compression cable; that is, take the pipe of the latter and pull into it preimpregnated paper-insulated cables and apply high gas pressure to fill all the spaces in the insulation with gas. It differs from the Oilostatic system, in that, the latter has oil as the pressure medium, and oil is forced into all the spaces in the insulation. As the oil is gas-free, when pumped into the pipe which has been previously evacuated, and fills all voids, there is no worry about ionization taking place, so that we do not have a critical electric stress at which ionization will start.

We do not consider it necessary to lay up the three conductors in the Oilostatic cable, because there is free movement in the pipe to take care of the longitudinal thermal expansion. The authors found this to be so for their cable. The testing of a 50-foot length for the end thrust as described in the compression-cable paper is inconclusive, as the length is too short as compared to actual installation. Actually we have at least several hundred feet between joints, and on installation we have noted a gradual turning as the cables are drawn in, giving the equivalent of a long lay cable which will result in radial expansion of the three conductors instead of longitudinal, as they are not bound together, and so are free to move radially.

My comments on lack of thermal data in the compression-cable paper also apply here. The authors stated that they have collected a great deal of data; yet they do not give us this necessary information to understand properly how to design this system. We are interested in the temperatures found for the conductor, shielding tape over the insulation and pipe. We would also like to see curves showing the temperature rise with time while the load is on and the rate of cooling when the load is dropped. I question very much the value of such short load cycles as 2.5 hours on and off, and four hours on and off. I doubt that the cable will arrive at its maximum temperature at all. Information on the 190-hour load-cycle test would be helpful in appreciating what this system is capable of doing in the way of taking care of heavy loads. We will be interested to compare the heat-storage capacity of this cable with the heat-storage capacity of the compression and an Oilostatic cable.

The information regarding soil thermal resistivity is very interesting. I am glad that the authors state the formula in the third paragraph is empirical. We have used a sphere in making thermal-resistivity tests and the well-known sphere formula. The values of soil resistivity given in Figure 4 are quite interesting and show fairly low values. However, the important thing is how do they use this thermal resistivity in determining the thermal resistance of the earth term for the total thermal resistance of the system?

The coefficient of friction of 0.37 for pulling the cables into the pipe up to 1,500 feet is very good considering it is a dry pipe. We have found for the Oilostatic system for lengths of 2,000 feet and more a value of 0.26. We have no hesitancy in pulling as high as 4,000 feet of cable without excessive strains on the conductors.

E. H. Kirkham (Phelps Dodge Copper Products Corporation, Yonkers, N. Y.): Under some circumstances it is desirable that a pressure relay be installed at the far end of a gas-filled cable when gas feeding from one end only. In the event that the feeder is operating as a closed system this relay will function equally well at either end. However, should it be necessary to operate with a constant supply of gas from a cylinder through a regulator, while the regulator will maintain a relatively steady pressure at the feeding end, pressure gradient in the cable may be such as to result in a dangerously low pressure at the far end. In one instance, this occurred with a leak in the order of one-half cubic foot per minute when fed at 12 pounds per square inch from one end; the pressure at the far end was measured at six pounds per square inch. Of course, the temporary feed was supplied at the far end pending location of the leak.

I agree with Mr. Shanklin that it is not necessary to "blow out" gas-filled cable equipped with a solid tube, but experience has shown that the excess compound should be drained from the joints periodically, a procedure which has the same effect as blowing out the cable.

At the present time, field experience indicates that this need not be done oftener than once a year, and probably, as the free compound is eliminated from the cable, the period may be extended.

E. R. Thomas (Consolidated Edison Company of New York, Inc., New York, N. Y.): There has been another type of compression cable described before the Institute which was not mentioned in paper 42-133. This was my paper on sheath-compensated cable presented before the winter convention

several years ago. The cable described at that time has operated satisfactory at pressures up to 100 pounds per square inch.

From an operating viewpoint several points in the compression-cable paper are of interest. First, the increase of several hundred per cent in the life of the lead sheath, when subjected to diaphragm action, by the elimination of oxygen from contact with the sheath surface, seems to be of practical value. We have occasions in New York to run cables over bridges and other vibrating structures and would like to inquire whether the fatigue strength would be similarly increased under these conditions by the elimination of oxygen from contact with the sheath surface?

Frequently cracked sheaths occur, particularly in the smaller manholes, from longitudinal movement and concentrated bending. Would it not be possible to reduce the cable fault rate from this cause by sealing the sheath surface from oxidation at these vulnerable points?

It was also pointed out in this paper that longitudinal movement was negligible when single-conductor cables were cabled together with a short lay and no external covering used. Under certain conditions such a procedure applied to duct installations may provide a simple solution to the problem of longitudinal movement and its effect on the lead sheath.

The Consolidated Edison Company of New York has made a number of laboratory and field tests on three-conductor cables of special construction for determining the ability of such cables to absorb within the sheath the longitudinal expansion of the conductors. Cables made with short lays, special binder construction, and sheaths of different degrees of looseness were tested. Laboratory tests showed that the greatest gain in reducing the restraining force necessary to prevent longitudinal movement was obtained by using short lays. Field measurements on a number of cable sections having special binder construction and short lays showed cable movements on these sections to be considerably smaller than for equivalent sections of standard construction.

There are several items in the paper on compression cable that the authors may clarify by answering the following questions:

1. How are countersunk type of connectors applied to a cable joint?

2. In Figure 5 of the paper, is the step on which the joint sleeve ends the lead sheath of the cable? If it is, what is the next higher step on the cable?

3. Since a void is left at the end of the cable sheath in the joint, is there any tendency for the joint sleeve to buckle and put undue strain on the wipe when external pressure is applied?

4. What is the 60-cycle dielectric strength of the cable, as compared to that of the joint?

From the standpoint of simplification, high-pressure gas-filled cable seems to approach more nearly the dream of the operating man than any cable available for such high voltages. The test data are very illuminating and convincing. If the future operating record proves as highly satisfactory as is indicated to date, I think high-pressure gas-filled cable will be hard to compete with.

Of particular interest is the fact that pipe cable was well adapted for installation under city streets in a city of the size of Detroit. Under such conditions of installation, I should like to ask how the cost of such a pipe system compares with the conventional duct system and also, how much of this seven-mile pipe system was under paved city streets, as well as what type of street paving was used.

The measurements of soil thermal resistivity are not only interesting but very helpful because of the lack of exact knowledge on this subject. In many cases in this country 80 degrees centigrade per watt per centimeter cubed has been used as the net value for soil resistivity. The variation shown by the Detroit data, from 75 to 120, indicates that 80 is probably not a very conservative figure to use.

H. C. Frank (General Cable Corporation, Bayonne, N. J.): Some supplementary data in connection with the laboratory tests of diaphragm action of lead sheath, mentioned in the paper on 120-kv compression-type cable, are significant. The daily load cycle, it will be recalled, was simulated by a laboratory cycle of 4.8 minutes. Because of the shortness of the laboratory cycle, it was a real problem to insure that the lead sheath would move uniformly throughout its length.

It became apparent that very little volume change takes place until nearly the full-pressure differential is established. Arrangement was therefore made to establish substantially this full-pressure differential in the first one third of each half-cycle. Thus, two thirds of each half-cycle was utilized for producing volume changes in the cable at substantially full pressure.

Experiment showed that this arrangement resulted in uniform longitudinal distribution of diaphragm action, as evidenced by breaks and general damage to the sheath occurring no more frequently at the ends of the samples than elsewhere.

One projected application of the compression-type cable involved installation on a bridge carrying heavy traffic and under severe vibration. Experiments were made as to the feasibility of such an installation and the results are pertinent not merely to this type of cable but to installation of any ead-sheathed cable on a vibrating structure.

Samples of pure lead sheath, about four feet long, two inches in outside diameter, and having an 85-mil wall, were supported at both ends by trunnions and vibrated at their natural frequency (about 1,000 cycles per minute) by means of an electrically powered vibration motor. The amplitude of vibration could be regulated.

The modulus of elasticity, as calculated from the physical dimensions, mass, and experimentally determined frequencies, was found to be constant over a wide range of amplitudes (for the frequencies used in the tests) and to have a value of 1.7 to 1.9×10^6 pounds per square inch for common lead. The peak vibration stresses were readily calculated from this modulus, the physical dimensions, and the amplitude.

The curve showing cycles of life as a function of vibration stress was found to be asymptotic to a line parallel to the life axis. A sample will fail in a limited number of vibration cycles if stressed beyond this asymptotic value but will last indefinitely if the vibration stress is held below this value. For pure lead protected against oxidation the asymptote was found to be 500 pounds per square inch. When oxidation was not prevented, the value dropped to 350 pounds per square inch.

During these tests it was attempted to determine whether unbalanced stress would affect the fatigue limit. It was found that the fatigue limit was unaffected since no unbalanced force could be supported by the sheath when under considerable vibration stress. The sheath would creep rapidly until all such unbalanced forces or stresses were removed. It follows also from this that there can be no complications caused by residual stresses being superimposed upon vibration stresses.

G. D'Eustachio (General Cable Corporation, Bayonne, N. J.): Mention is made in the paper on 120-kv compression-type cable of the injurious effect of oxidation on diaphragm action. Specifically, the substitution of nitrogen for compressed air as the pressure medium in these tests resulted in increasing the life of laboratory samples by a factor of 4.

This effect of oxidation is in line with the generally known fact that corrosion of metals greatly hastens their destruction by fatigue. The following is offered as an explanation of the mechanism involved.

When a fresh surface of lead is exposed to air, a thin coating of oxide is quickly formed. Normally, this acts as a protection against further oxidation. However, in a sheath subjected to vibration or diaphragm action, the brittle oxide film is readily broken, and a fresh surface is continually presented to the effect of oxidation. Repeated bending tends to concentrate the action in definite cracks which ultimately penetrate the entire sheath.

William A. Del Mar (Phelps Dodge Copper Products Co., Yonkers, N. Y.): In the year 1935 I visited many of the principal cities of the United States and spoke before local engineering organizations on compression cable, exhibiting a motion picture of the then recently completed compression-cable system at Copenhagen in Denmark which I had seen under construction.

Engineers discussed this system at these meetings and the discussion was nearly always in one vein. They said, in effect:

"We have troubles on our cable systems and troubles on our high-pressure pipe systems. Now you describe a system that will combine these two kinds of trouble on one system. We prefer to take our troubles singly."

Ten years after the first European installation the Detroit Edison Company takes the plunge and decides to take on both kinds of trouble in their regular stride.

The type-*H* cable, also was held in abeyance except for one installation for about 10 years after its European introduction.

I have made my appreciative comments on the low-pressure gas-filled cable in the discussion of Mr. Shanklin's 1939 paper and will now confine myself to a few critical comments on some of the details.

Both Doctor Wiseman and Mr. Mildner in that same discussion, asked why Mr. Shanklin used average rather than maximum stresses in designing his insulation thicknesses.

I am one of those who believes that the maximum stress, as ordinarily calculated, is of doubtful significance in many cable problems where it has been used indiscriminately in the past, but it seems to me that the gas-pressure cable, at operating voltage, is one case where there can be little doubt of its applicability.

Mr. Shanklin seems to agree with this, for in his reply to Mr. Mildner he said:

"Mr. Mildner is correct in stating that it is better to deal with maximum voltage stress than average voltage stress. Most of the cable lengths we tested had compact sector conductors with relatively sharp corners. For conductors of this shape it is difficult to express maximum voltage stress accurately, and it is for this reason that average voltage stress is generally used as a practical yardstick in the United States."

Thus, while Mr. Shanklin recognized in 1939 that the maximum stress should be used in the design of gas-pressure cables, and that this was not done only because of the difficulties, he continues to use the average stress for design purposes in his present paper.

Let us see where this leads us in a specific case.

Assume a 350,000-circular-mil 34,500-volt sector cable with the wall thickness recommended for this voltage, namely, 310 mils.

The average operating stress will be 64 volts per mil, and Mr. Shanklin considers this to be a satisfactory basis of design. We have studied the stress around the contour of a 350,000-circular-mil cable with 312 mils of insulation, using the electrolyte method, and have shown the results as a graph.[1] Reference to this graph will show that the stress at the surface of the conductor at the shoulders of the sector is 1.7 times the average stress, or 109 volts per mil, neglecting strand effect.

It is well known that ionization starts, in a drained cable, at a maximum stress of 50 volts per mil at atmospheric pressure. Mr. Shanklin's Figure 5 indicates that this is increased by a factor of 1.63 at 12 pounds gas pressure, that is, to 81 volts per mil.

We thus, have a cable operating at a stress of 109 volts per mil which is 35 per cent greater than its initial ionization stress of 81 volts per mil. It therefore appears that the low-pressure gas-filled cable takes about 70 per cent advantage of the 50 per cent increase in stress permitted by the self-extinguishing effect, and therefore Mr. Shanklin is only literally accurate but really somewhat misleading in saying that this effect "offers an additional factor of safety." In fact, he appears to recognize this, in the next sentence, by admitting that the self-extinguishing effect "allows working voltage stress to more safely approach the critical voltage stress at which cumulative ionization deterioration occurs."

It would help an understanding of this important type of cable if Mr. Shanklin would clarify this matter of voltages stresses, in detail, in the light of his experience and research.

Mr. Shanklin's statement that he has "tried about all of the recognized available types of high-viscosity compounds, including rosin mixtures, and so forth" is probably a more comprehensive statement than he intended it to be, as each laboratory has its own line of development which overlaps with others to some extent but, in the main, proceeds along independent lines, with its own materials, processes, equipment, and methods of test.

I cannot help believing with Mr. Faucett and associated authors, that some of the recognized and maligned blended oils will give better results than the so-called "standard all-mineral compound used for some time past." This last-named compound is capable of becoming electrically unstable as the result of contamination in the impregnation process and should be easily surpassed, for this service, by compounds more permanently immune to ionization.

Also, the particular oil referred to by Mr. Shanklin is entirely incompatible with rosin or rosin derivatives, and cables made with such mixtures are quite unstable, a fact which may explain his aversion to the blends.

Table I

Faucett, Komives, Collins, and Atkinson	Shanklin
1. The saturant used in the Detroit cables has a very high viscosity	Optimum viscosity is 100 Saybolt at 100 degrees centigrade. (This is about the lowest viscosity ever used in solid-type cables)
2. Since it was desirable not to expose the insulation to the atmosphere any longer than necessary, and so forth	Cable exposed to air for eight hours had good endurance at 120 volts per mil but had increased dielectric loss
3. Very thin tapes result in increase of dielectric strength	Ionization voltage with three-mil paper was no higher than usually obtained with standard six-mil tape. Life test with three-mil paper "little if any longer"
4. Cable with thin paper withstands, without damage, normal bending	Thin paper tends to wrinkle and will not withstand cable-bending as well
5. Strand shielding of *SMD* cable believed responsible for its having higher dielectric strength than unshielded oil-filled cable	Ionization voltage same with and without strand shielding, and time to stabilize at 85 volts per mil same

Data on impulse dielectric strength given by R. Davis[2] indicate that highly drained cable at atmospheric pressure has an impulse strength of only about one-third that of normally impregnated cables. This points definitely to the desirability of using viscous compound to obtain minimum drainage and maximum impulse strength.

Mr. Faucett and his associate authors do not share Mr. Shanklin's belief in a low-viscosity impregnant. On the contrary, they are insistent on the use of one of "very high viscosity."

This brings me to the very interesting contrast between the views of these authors on several important points as shown in parallel columns in Table I.

Turning now to paper 42-135 by Faucett, Komives, Collins, and Atkinson, we find a cable system which is virtually the Oilostatic system without the oil and oil-pressure accessories. It should therefore be interesting from a first-cost standpoint.

Whether it will prove economical eventually may not be known for years, depending on how much cable is ruined by water entering the pipe, how much will be perforated by transient voltages or even working voltages in the event of loss of gas pressure. The Detroit Edison Company deserves the thanks of the industry for taking these risks in the interest of progress.

Table II

	Power Factors—Degrees Centigrade 85	25
At beginning	0.76	0.42
After 100 load cycles	2.47	0.41

The paper gives a great deal of interesting information among which the data on soil resistivity may be especially noted.

The formula, $g = 128/W(T_1 - T_2)$, while empirical, is derived from the following rational formula for a sphere:

$$G = \frac{4\pi r}{W}(T_1 - T_2)$$

where r = radius of sphere, and the other quantities are as given in the paper. This formula is based on the assumption that heat is dissipated equally, in all directions, from the sphere.

On the other hand, the Kennelly formula for heat resistance from a cable or pipe to ambient is based on the assumption that the heat is all dissipated upward. It is, therefore, obvious that the constants obtained by the authors' tests cannot be used directly in the Kennelly formula for determining the thermal resistance from pipe to ambient.

The formula for the test electrode gives a lower soil resistivity than the true one, because more watts are expended in driving heat through the nonuniform actual path than through a uniformly radial path.

On the other hand the Kennelly formula gives a falsely high resistance, because it neglects the very considerable amount of heat which flows in other directions than upward.

Therefore, if we use an unduly low resistivity in the Kennelly formula, we tend to counteract the falsely high resistance which that formula gives. Judging by *BEAIRA* publication *F/T*128, these errors cancel, for all practical purposes, as we find, that the usual correction factor of $^2/_3$, used in connection with the Kennelly formula, in British practice, is "*unnecessary when the thermal resistivity of the ground is measured in situ by one of the methods described in the appendix.*" This is very important to note in view of existing controversies on soil resistivity.

For some years past I have been contending in favor of the use of a soil resistivity of 180 for standard carrying-capacity tables, using it in the Kennelly formula with the

Table III

	Power Factors—Degrees Centigrade 60	25
At beginning	1.23	0.45
After 20 load cycles	1.44	0.47
Increase, per cent	17	4.5

usual correction factor of $^2/_3$ so as to give a net value of 120.

Others have contended for a net value of 80 or less for this purpose.

The data presented in Figure 4 of the paper indicate the following safe net values, all of which are to be used *without* the $^2/_3$ correction factor.

Porous loam	100
Clay	105
Sand	120

This suggests a basis of compromise on a net value of 105 except for sandy soil, for which a net value of 120 should be used.

Values as low as 80 are attained only with porous loam during the three coldest months and are, therefore, unsafe.

It should be noted that these values would have to be increased something like 50 per cent for comparison with resistivities, derived from measurement of soil between definite boundary plates, such as given by Shanklin.[3]

The authors use, as criterion of stability of their cable, the power factor at room temperature or less, giving as reason that "it was not feasible to obtain power-factor measurements at elevated temperatures, since it required a relatively long time to switch the experimental cable out of the circuit and connect up the power-factor measuring equipment." This reason seems somewhat inadequate, as it is well known that room-temperature power-factor measurements are not a sensitive indication of deterioration. Data on cables life-tested in accordance with the procedure described by Boehne and Linde (page 207 of reference 4) are typical of results on laboratory made samples of definitely unstable character, as shown in Table II.

Similarly a cable of poor quality, life-tested in accordance with the procedure described on page 209 of reference 4 gave the results shown in Table III.

Here the room temperature reading showed some change but only about one-fourth that at 60 degrees centigrade.

The instability of these cables would have passed unnoticed if room temperature power factors had been relied upon.

J. A. Peterson (The Commonwealth and Southern Corporation, Jackson, Mich.): Three types or methods of installation of high-pressure gas-filled cable are mentioned in paper 42-135:

1. Method used by the Detroit Edison Company
2. English method with reinforced lead sheaths.
3. Oil-filled (Oilostatic) method.

Is there any information available as to the relative costs of these three methods?

It will be interesting to know the expected life of the iron pipe treated with one-half-inch Somastic as used in the Detroit Edison method.

The data on soil thermal resistivities constitute very valuable information, especially to the Detroit Edison Company, but it would be more valuable to the industry as a whole if the actual moisture content of the various types of soil were known for the different values of thermal resistivities. Was this point checked at the time the tests were made?

It would be interesting to know how conductor expansion is taken care of on this installation—by the lay of the cable, by the snaking effect of the cable in the pipe, by expansion bends, or by a combination of these methods. The report states that in the experimental installation the expansion of the iron pipe was taken care of by expansion bends. Was this method used for the entire installation?

The viscosity of cable-impregnating oil used in low-voltage solid impregnated-paper lead-covered cable ranges ordinarily from 100 to 150 seconds Saybolt Universal at 100 degrees centigrade. The viscosity of the oil used in the gas-filled cable is given as 3,000 seconds Saybolt Universal at 100 degrees centigrade. What is the viscosity of this latter oil at 50 and 150 degrees centigrade? What is the maximum temperature at which this cable is expected to operate? Will this impregnating oil remain in the insulation, or will it gradually drain out into the pipe, and, if it drains into the pipe, will it be necessary to drain the oil from the pipe? It is possible that the oil will remain in the insulation and that none of these points present any problem.

Johnstone Wright (Central Electricity Board, London, England): The first departure from conventional solid-type underground-cable practice in Great Britain was an extensive application of oil-filled cables in sections of the British Grid. Such oil-filled cables were used at 66 kv and 132 kv. They have been quite successful, but their use is attended by certain disadvantages, particularly where the contour of the cable route includes steep sections. We were, therefore, interested in any developments which would minimize these difficulties and at the same time be economically attractive.

A gas-pressure cable of the Hochstadter type was, therefore, laid in a London area and put into service on October 1, 1932. This cable was laid in a steel pipe which has given rise to a certain amount of electrolytic corrosion trouble. The source of this trouble was discovered and the necessary remedial measures instituted, and subsequent experience has been all that might be desired. We are, nevertheless, somewhat apprehensive regarding the possibilities of corrosion in steel pipes, and a subsequent gas-pressure cable in the same area is of the double-lead-sheath type. At no time has there been any electric fault on either of these gas-pressure cables.

When the internal gas-pressure cable was mooted, we took a close interest in its development, and when all the necessary works proving tests had been satisfactorily carried out, we put a one-mile trial length of 132-kv cable into service as a field experiment. This cable went into use on December 4, 1937. It has carried the loads, short-circuit currents, and surge stresses encountered during the intensive bombardment of London without trouble. The cable was on one occasion damaged during street excavation, and the necessary repairs were effected expeditiously, the circuit being put back into service much in the same way as is done in everyday conventional mains practice.

The success of this experimental cable led us to utilize the same type of two further short 132-kv routes where it was impracticable to have overhead lines. We are now engaged in the final stages of making a seven-mile circuit of 132-kv gas-filled cable.

This outline cannot do justice to the excellent work which has been done by the manufacturers in producing economical and reliable 132-kv underground cable, but the detailed story must be left to be told when conditions become more normal.

L. Meyerhoff (General Cable Corporation, Bayonne, N. J.): The information contained in the paper on 120-kv high-pressure gas-filled cable regarding temperature stability is amplified and brought to date by the following.

Two lengths of cable representative of that furnished for the commercial run were cut up into a number of 12-inch lengths. These were individually sealed in lead pipe, the free space in the pipe being filled with nitrogen at about five pounds gage pressure. The sealed samples were then placed in an oven and maintained at 100 degrees centigrade. Samples were withdrawn at intervals for test purposes.

In addition to the above samples, two samples from each length were equipped with electrodes and guard rings before being sealed into the lead pipe, and leads were brought out through insulating bushings so as to permit electrical measurements to be made at 100 degrees centigrade during the progress of the aging run.

In Figure 2 of this discussion is shown the variation of power factor at 100 degrees centigrade with time of aging on the four last mentioned samples. It will be noted that the power factor after 220 days of aging has changed very little, what change there is being apparently in the direction of improvement.

Figure 3 shows the temperature-power factor data for several samples of one of the cables, tested after various aging times up to 184 days. The points for all the samples (including the unaged cable) are represented very well by a single curve. The variations between these samples are no greater than would be expected of a similar number of individual samples of new cable.

Figure 4 shows the radial power factor at 80 degrees centigrade for the cable in its original condition and after 40, 113, and 184 days of aging. It will be noted that in the

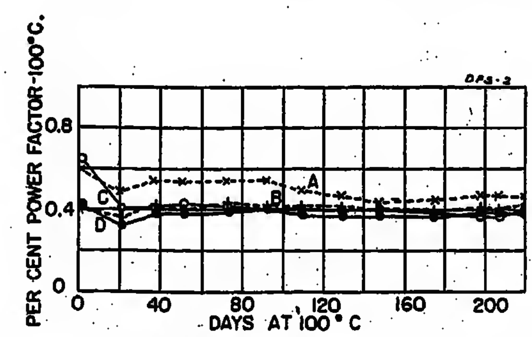

Figure 2. Power factor versus days of aging at 100 degrees centigrade

A, B, C, and *D* represent four similar samples

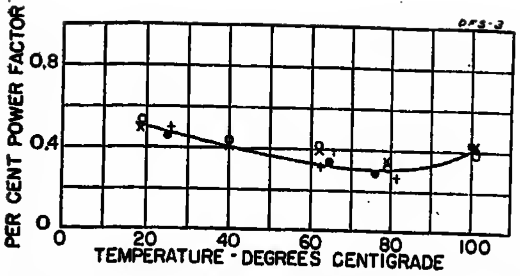

Figure 3. Power factor versus temperature
Showing effect of aging at 100 degrees centigrade for 184 days to be insignificant

× New cable — + Aged 113 days
○ Aged 40 days — ● Aged 184 days

main the radial power factor is quite flat in all cases and that such changes as appear are in the direction of reduction rather than rise of power factor. In the case of the last two samples withdrawn there appears a slight rise in power factor near the sheath. Whether this rise is due to the aging or is characteristic of the particular samples will not be known until further samples are withdrawn and tested.

In Figure 5 the tensile and tearing strength values have been plotted for the new cable and for a sample which had been aged for 184 days. It is apparent from these results that there is no material change in mechanical strength. The sharp change at 20 per cent distance from the conductor coincides with a change in the type and thickness of the paper.

Thus, from all the standpoints studied there has been no significant change in the electrical or physical properties of the cable during more than six months' aging at 100 degrees centigrade.

I should like also to discuss the benefit of using thin paper in gas-filled cable. Our tests have indicated that gas-filled cable with thin paper has considerably higher breakdown strength than similar cable with thick paper, particularly on short-time and surge tests. The difference in strength appears to be greater than can be justified on the basis of the increase of the specific breakdown strength of gas, by reason of the reduction of the gap distance. From the published data, the breakdown strength of a 2.5-mil gap of air at 200 pounds pressure is about 12 per cent higher than that of a five-mil gap at the same pressure, whereas gas-filled cable made with 2.5-mil paper is apparently considerably more than 12 per cent stronger electrically than cable made entirely with five-mil paper. Thus, the above explanation seems numerically inadequate.

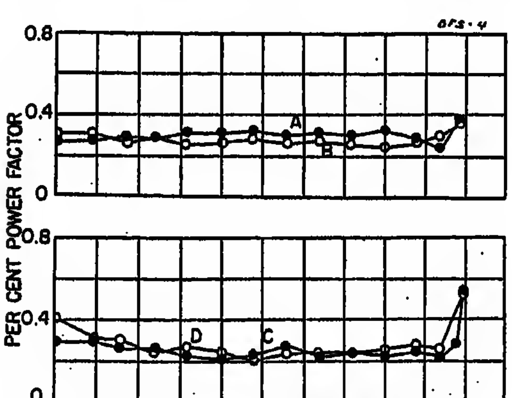

Figure 4. Radial power factor as affected by aging at 100 degrees centigrade

A. New cable — C. Cable aged 113 days
B. Cable aged 40 days — D. Cable aged 184 days

What appears to be a more adequate explanation is the following. The benefit of the thin layer does not lie so much in the voltage at which the gap breaks down as in the reduction of the amount of energy dissipated in any gap after it breaks down, that is, above ionization voltage.

Compare two cables of the gas-filled type, one, cable A, made up of five-mil paper and the other, cable B, of $2^1/_2$-mil paper. Assume the power-factor versus voltage characteristics of the two cables as a whole to be identical. Thus, at any voltage above the ionization point, the total energy dissipated in all of the gas spaces will be the same in cable A as in cable B. However, since cable B has twice as many gas spaces as cable A, the energy dissipated in any one gas space of cable B will be only one half as much as in a similarly placed gas space of cable A. This means that in any $2^1/_2$-mil space there is only one half as much energy ready to bombard and start to burn the paper and oil or to find a path around the paper as in a corresponding five-mil space.

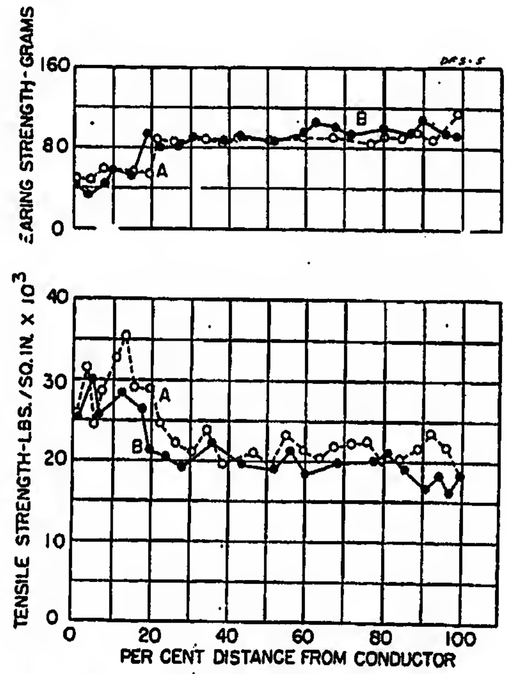

Figure 5. Mechanical strength of insulation as affected by aging of cable at 100 degrees centigrade

A. Cable aged 184 days
B. New cable

Dawes[1] has found that the energy loss caused by the ionization of the gas spaces in a cable may be represented approximately by the expression $K (E - E_0)$, where K is a constant, E the voltage applied, and E_0 a voltage substantially equal to the ionization voltage. Thus, in order for the energy in one gas space to be the same in the two cables, $E - E_0$ must be twice as great as in the case of cable B as in the case of cable A. For instance, if E_0 is 140 kv for the two cables, 200 kv applied on cable A will produce the same amount of energy in a given gap as 260 kv will produce in a corresponding gap of cable B.

In the above discussion it was assumed that the power-factor versus voltage characteristics of the two cables are the same. As previously stated, however, at 200 pounds per square inch a $2^1/_2$-mil gap begins to ionize at a 12 per cent higher voltage than does a five-mil gap. Thus, in changing from five-mil to $2^1/_2$-mil paper there is a gain in breakdown strength of this 12 per cent plus the additional gain indicated in the above discussion. The amount of this additional gain will depend on the ionization characteristics of the cable and on the voltage applied.

In tests of long duration the value of $E - E_0$ is small, so that the gain in strength caused by the use of thin paper in such tests may be substantially only that, caused by the increase in ionization voltage. In short-time tests, however, $E - E_0$ is large, and the gain in strength will be very considerable. On the basis of this analysis, the gain should be even more marked in surge tests. It should be noted further that at lower gas pressures, say 30 pounds per square inch, a given amount of gain due to the thin paper will occur at a lower voltage than at the high pressure because of the large reduction in the ionization voltage. This fact makes it feasible to test cable with $2^1/_2$-mil paper for acceptance purposes at much lower pressures than would be permissible for cable with five-mil paper.

1. Ionization Studies in Paper-Insulated Cables—II, C. L. Dawes, H. H. Reichard, P. H. Humphries. AIEE Transactions, volume 48, 1929, pages 383–98.

C. Beaver (W. T. Glover and Company, Ltd., Manchester, England): The authors of paper 42-135 and all concerned are to be congratulated on the successful introduction into the United States of the high pressure gas-filled cable on a commercial scale. It is to be hoped that it will have an operating experience similar to that of gas-filled cable in England.

It is, of course, essentially the same cable but differs in the method of installation and in this important respect would appear to carry a greater burden of risk. That is to say, the difficulty of maintaining long lengths of pipe line free from leakage under high gas pressure would appear to be considerable, whereas experience shows that perfect freedom from leakage is obtainable with the reinforced sheath type. In actual practice in England no supplementary gas supply is ever necessary after the initial charging.

Under conditions of laying and installation obtaining in England, it is very doubtful whether the pipe-line method would ever be used; the self-contained perfectly gastight reinforced sheath type having everything in its favor from the user's point of view, that is, embracing economical, technical, installation, and maintenance aspects.

The substantial character of the protective coatings of the pipe is noted, but it has to be remembered that in the presence of vagabond currents in the vicinity of a minute imperfection or damage the current density at such a point might be relatively high and corrosion correspondingly rapid. In other words, the very excellence of the protection from ordinary chemical attack entails possible susceptibility to concentrated electrolytic corrosion.

It is gratifying to note that the authors consider this type of cable to be at least equal, electrically, to the oil-filled cable, and

that, physically, the type is superior to the oil-filled cable in that

(*a*). No draining or migration of the impregnating oil is encountered, so that stop joints or other devices are not required.

(*b*). No allowance has to be made for impregnating oil expansion so that oil reservoirs are not necessary.

In the reinforced lead sheathed cables such as have been installed in England the maximum operating conductor temperature is 80 degrees centigrade, and at this temperature the gas-pressure rise is such that the gas density at the conductor surface, where the electric stress is highest, is approximately equal to that at 15 degrees centigrade, and in consequence the ionization voltage is substantially the same at 80 degrees centigrade as at 15 degrees centigrade. (It should be noted that these cables are sealed off and are not in communication with gas reservoirs at the terminals.) In the pipe form of the cable the gas-pressure value at high-conductor temperature will not increase proportionately to the absolute temperature, and hence the ionization voltage will be lowered at high-conductor temperature. This is fundamentally due to the fact that the average temperature of the gas-filled system in the pipe type of cable does not increase much with increase of conductor temperature.

The authors have given the reasons for the radial grading of the paper thicknesses in a very clear and concise manner. In England the thinnest paper tapes used at present are $1^3/_4$ mils thick, and the ionization voltage at 200 pounds per square inch by gauge of a 600,000-circular-mil round conductor cable insulated with 600 mils of paper, of graded thickness $1^3/_4$ mils to $5^1/_2$ mils, would be 165 kv minimum between conductor and sheath, the permittivity of the dielectric being 2.9 to 3.0. Cables have operated at maximum stress values of 335 volts per mil at 200 pounds per square inch by gauge in England for nearly five years as compared with the value of 288 volts per mil at 255 pounds per square inch by gauge for the installation described in the paper.

It has long been known that increasing the density of paper results in high breakdown voltages in solid-type dielectrics. In the gas-filled cable a particular advantage accrues under impulse voltage conditions, because the gas-filled spaces shunt their stresses to the solid (impregnated-paper) component of the dielectric, and the breakdown occurs due to disruption of this part of the dielectric.

As a matter of fundamental design the provision of conditions which suppress ionization up to twice working voltage also provides the dielectric with an asymptotic a-c time–breakdown value sufficiently above the working voltage to take care of such margins as manufacturing variations and installation exigencies, together with sufficient impulse strength to resist the maximum impulse voltages encountered in service.

The authors' work on the latter aspect is very valuable as showing the influence of various factors on the impulse strength of the gas-filled dielectric.

No data are given in the paper as to permittivity and thermal resistivity values. In the cables installed in England the permittivity value is 2.9 to 3.0, while the thermal resistivity value is 700 thermal ohms per cubic centimeter. These cables are insulated with paper dried and preimpregnated in sheet form on a special vacuum paper serving machine (British patent 373,697). On this machine the impregnated sheet of paper is scraped, while hot, by means of heated knives, so that all excess or free impregnating compound is removed. The roll of impregnated paper 15 inches in diameter and 36 inches wide is split into spools and then lapped on to the cable in air with no control of the humidity. The power factor–temperature characteristic is practically identical with that given in Figure 12 of the paper. The cables insulated with this paper can be successfully subjected to mine-shaft cable drainage tests at 80 degrees centigrade.

The authors' remarks in the third paragraph of the section dealing with dielectric strength, regarding the origin of the failures under prolonged a-c tests are interesting.

We have also noticed in similar tests using high-impedance circuits and short time relays to limit the burning at the fault that the puncture generally occurs in the gas-filled space within a distance of ten mils from the edge of the paper strips for gaps width of the order of 60 to 100 mils. We attribute this location of the fault to the fact that the thickness of the gas space here is equal to the paper thickness, whereas toward the center of the gap width the thickness of the gas space is reduced because of bowing of the paper strips bounding the gap.

Referring to Figures 10 and 11, the data given show the effect of moisture on the high-temperature power-factor values and also the effect of control of humidity during the lapping process. According to English manufacturing experience, however, it is not necessary to control the humidity in order to produce power-factor values equal to those of curve *A* in Figure 10.

Further, the absence of free impregnating oil in the gas-filled cable eliminates the possibility of metallic contamination of the dielectric by the copper-conductor screening tape, or lead sheath during temperature cycles. This phenomenon has of course been noted frequently in cable in which the dielectric is filled with oil.

I note that there is little reference in the paper to physical features except with regard to paper density and viscosity of the impregnating medium, and perhaps, without being too elementary, I may be allowed to point out that the high-pressure gas-filled cable—at least in its reinforced sheath form—has an important physical basis of design. It strikes at the root of the ionization troubles which limit the use of solid-type cables, by substituting completely reversible conditions of expansion and retraction inside the confines of the cable sheath for the partially reversible conditions which are responsible for the said limitations.

In providing for expansion and contraction at constant volume it also obviates "cold working" of the lead sheath—a result not obtained in any other type of cable.

The corollary is that the original conditions established in the cable, as regards freedom from ionization, are never subsequently infringed.

In conclusion, the authors' figures for mileages of high-pressure gas-filled cable installed in England may be brought up to date as follows:

Installed:
132 kv—6.5 conductor miles
33 kv—52 conductor miles
(A considerable proportion of this has been in service 5 years.)
Proceeding, about to be put into service:
132 kv—18 conductor miles
33 kv—25 conductor miles

G. B. Shanklin (General Electric Company, Schenectady, N. Y.): My discussion of the two papers by Faucett, Komives, Collins, and Atkinson will deal chiefly with the high-pressure gas-filled type of cable, but I will first comment briefly on the compression-type cable.

We made a close study of the latter type when it was first introduced about ten years ago. The main thing that discouraged us from further work along this line was the fact that safe operation of this design depended upon complete gastightness of the lead sheath, joint sleeves, and wipes. If high-pressure gas in the steel pipe, normally segregated from the cable by the impervious sheath covering, once enters the cable cross section through a haphazard leak, it will gradually saturate the impregnated paper and travel a long distance back in the cable length. Eventually at some distant point gas will replace impregnating compound forming a "dry spot." There is then no means of maintaining sufficient pressure at this point when temperature changes take place, and ionization trouble will occur. Experience with all cable systems indicates that it is not possible to avoid occasional leaks in the sheath envelope.

Concluding that eventual gas saturation and loss of pressure control in compression-type cable were unavoidable in any case, we reasoned that it would be better to accept this fact at the beginning and use gas-filled insulation directly exposed to the high-pressure gas in the steel pipe. In this way full control of pressure could be maintained both radially and longitudinally; also, it represented a simpler and more economical design of pressure pipe cable.

Following out this idea we started initial development work in 1932, the principles of which are described in United States patent 1,991,230, filed in July 1933. Some of the test results are outlined in a paper, "Low-Gas-Pressure Cable,"[1] which I presented at the AIEE winter convention in 1939. Further details relating to this cable system are given in a second paper which I presented at this afternoon's meeting, contemporaneously with Faucett, Komives, Collins, and Atkinson's paper, "120-Kv High-Pressure Gas-Filled Cable."

The cable systems described in these two papers are closely the same in principle, the only difference being the use of mass-impregnated-paper insulation in one case and preimpregnated paper in the other. In pointing this out, I have no desire to detract in the slightest from the credit due Faucett, Komives, Collins, and Atkinson for the initiative they have shown in going ahead with the first full-sized installation of this kind and the perfection of practical detail it involved. They are heartily congratulated for carrying on to a finish the fine job that was done.

On purely technical grounds I am won-

dering why Mr. Faucett selected preimpregnated paper in preference to regular mass-impregnated-paper insulation for his system, although I readily admit that at 200 pounds nitrogen pressure either type is safe for 120-kv service. The reason for this is that the electrical strength of nitrogen gas at 200 pounds pressure is almost as great as that of the solid insulation.

H. M. Hobart of our company demonstrated this in his development of a high-pressure gas cable system in which bare rigid copper conductors were held in place in a steel pipe by insulator spacers at intervals. Installation difficulties and low impulse strength were the factors that prevented commercial use. Sixty-cycle strength was sufficient for 138-kv service at pressures in the order of 200 pounds and above.

Dry unimpregnated-paper insulation also has sufficient 60-cycle strength at 200 pounds gas pressure for high-voltage service. Low impulse strength and the difficulties of moisture absorption are its chief handicaps. It is absolutely essential to operate dry-paper cable well below the ionization starting voltage, which, at reduced pressure, is lower than that of impregnated paper because of the relatively large volume of void space involved. Ionization action in this

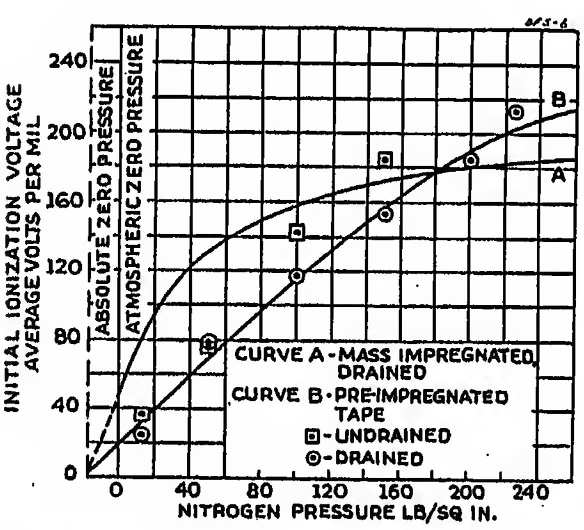

Figure 6. Voltage stress on solid insulation at which initial ionization starts in drained gas-filled cable

type of cable is cumulative, and failure will occur quickly after incipient ionization once starts.

Preimpregnated-paper tape applied dry without flushing compound, as used by Mr. Faucett, overcomes the difficulties of ready moisture absorption and low impulse strength, but in all other characteristics it is about midway between dry paper and mass-impregnated paper. At butt spaces, wrinkles, tears, and other such points of non-homogeneity, the void spaces are just as large as with dry unimpregnated paper. Ionization-starting voltage as a function of gas pressure is accordingly about the same, but incipient ionization is less dangerous because of the barrier effect offered by the impregnated tapes. It is important, however, to operate well below the ionization-starting voltage and eliminate any possibility of incipient ionization. There is no surplus compound surrounding the void spaces, which are not only larger for this reason but lack the ability to extinguish incipient ionization by wax formation and self-healing action.

This characteristic would be more clearly understood if Mr. Faucett had presented charts showing power-factor change and general behavior on long-time full-temperature load-cycle endurance tests at voltage steps always a little above ionization starting voltage. We are running such tests now at 200 pounds pressure on both mass-impregnated and preimpregnated insulation.

In the meantime Figure 13 of Mr. Faucett's paper plainly shows the trend of this characteristic for preimpregnated cable. Even at 225 pounds pressure the cable always failed in from 4 to 16 days at a voltage only a little above initial ionization-starting voltage. This proves a lack of self-healing action such as exists in mass-impregnated gas-filled cable. The latter type would not have failed at all under these conditions. Incipient ionization would have been extinguished, and the cable would have remained stable indefinitely, necessitating one or more higher voltage steps and a longer time to cause failure. Reference to the test charts in my paper will confirm this.

A comparison of initial ionization-starting voltage stress as a function of gas pressure tells the whole story. Such a comparison is given in Figure 6 of this discussion where the ionization data for preimpregnated insulation, from Mr. Faucett's Figures 8 and 9, are superimposed on a corresponding curve for mass-impregnated insulation, from Figure 5 of my paper. It will be noted that at 200 pounds pressure there is practically no difference between the two types of insulation. For 120-kv service either could operate safely at the usual average working voltage stress of 140 volts per mil, although gas pressure could safely drop much lower for the mass-impregnated type without danger of ionization trouble.

When the same comparison is made with low- and medium-pressure systems there is a wide difference and, in fact, the preimpregnated type of insulation is not economically feasible in this range because of the heavy wall of insulation that would be required. Low-pressure gas-filled cable of the mass-impregnated type operates at an average voltage stress of 65 to 70 volts per mil and average gas pressure of 12 pounds. The ionization-starting voltage stress of the preimpregnated type is less than half the required working voltage stress. Medium-pressure gas-filled cable, mass-impregnated, is designed to operate at 95 volts per mil, 30 pounds gas pressure. Here again the ionization voltage of the preimpregnated type is less than half the required working voltage stress.

In Beaver's high-pressure gas-filled cable with reinforced sheath, preimpregnated insulation was necessary, for he had no means of transmitting and controlling gas pressure along the cable length, other than the small butt spaces between tapes. In a high-pressure pipe cable system, however, far better pressure control exists than Beaver could ever hope for, and, in my opinion, the need of preimpregnated insulation no longer exists.

There is another important point to be considered. Aging studies with impregnated paper show that the rate of absorption when exposed to oxygen and moisture, as well as the rate of deterioration from this cause, are inversely proportional to the viscosity of the impregnating compound. For a given quantity of absorbed impurities, however, the ultimate results are the same. It merely takes a longer time to reach these results when heavy compound is involved.

This being so, it is just as important to exclude all traces of oxygen and moisture impurities in a system using preimpregnated insulation as in one using mass-impregnated insulation. Considering the much greater degree of surface exposure of preimpregnated tape from the start of production up to final sealing of the completed system in the field, I do not see how it is possible to exclude impurities to the same degree. This problem is common to all types of impregnated-paper cable and not to gas-filled cable alone.

If anyone doubts the importance of excluding oxygen and moisture he is referred to F. M. Clark's paper, "Factors Affecting the Mechanical Deterioration of Cellulose Insulation,"[2] presented at the convention day before yesterday. The effects of even traces of oxygen are already well known, but Mr. Clark's conclusion that insulation life is halved for each doubling of moisture content is not generally known.

E. Johansson (General Cable Corporation, Bayonne, N. J.): In the paper on 120-kv compression-type cable, breakdown values of 436 and 445 volts per mil of cable insulation are given for two joints tested. It may be noted that the joints used in these tests were not identical with the joints in the field installation but represented a stage in the development of the final joint. A subsequent test on a joint of the final construction produced a breakdown value of 602 volts per mil of cable insulation with the same test program and after a total time undervoltage of 11 hours.

The difference in performance between the two types of joint is explained by the construction, a small quantity of varnished cloth having been used in the first two joints but paper alone in the later joint. The copper conductors are elliptical, so that the cross sections of the two conductors to be joined will not line up normally. This discrepancy is accommodated by using a specially shaped twisted elliptical connector. In order to produce smooth insulation over the connector it was thought essential at first to use a few layers of varnished cloth next to the connector, but later development permitted satisfactory use of paper tapes even at the connector.

In applying paper tape to these joints, special care was taken to minimize access of moisture to the paper. The splicers wore rubber gloves, and the insulation was flushed with hot oil at intervals. As a result there was only a slight increase in the power factor of the tape when applied under severe conditions, that is, during the days in the summer when the relative humidity was high (65–70 per cent).

The following comments supplement the

paper on 120-kv high-pressure gas-filled cable:

One stop-joint for this cable was given a 60-cycle dielectric-strength test. The joint was first subjected to a constant voltage of 140 kv for 101 hours at 225 pounds per square inch gas pressure; then the voltage was increased five kilovolts every 24 hours to and including 180 kv, making the total time under voltage 293 hours. The gas pressure was then lowered to 100 pounds per square inch, and 140 kv was again applied for 34 hours without failure. The preceding test is well above the 170 kv for six hours required under the Association of Edison Illuminating Companies specification for samples of 120-kv oil-filled cable. The dissection of the joint showed no visible effects of electrical stress.

As stated in the paper, tests were made in the laboratory to determine the amount of drainage in the cable at high temperatures. A cable was heated to 100 degrees centigrade in a vertical position for 43 days, and the space occupied by the gas in the insulation was measured before and after heating. The proportion of the insulation occupied by gas increased from five per cent before heating to nine per cent after the 43 days of heating. This determination was made on a sample taken from the top of the inverted *U*, where the maximum drainage took place.

The paper describes incipient or arrested failures produced under test conditions. The following may be added concerning other characteristic appearances of these incipient failures. In a number of cases, burning or tree design was found in layers of paper remote either from the conductor or the sheath, and no apparent connection was found between these and the conductor or the sheath. However, on extraction of the compound from the tapes lying between the conductor and the failure, it was possible, by examination through a microscope, to find punctures in these tapes. These took the form of a large number of small holes and could usually be found in all tapes down to the conductor. It is felt that, while this connection was not actually found in all cases, a sufficiently careful and complete examination would have shown a puncture extending to the conductor in each case.

J. B. Whitehead (The Johns Hopkins University, Baltimore, Md.): Referring to the two papers on gas-filled cables, the results presented show a fine record of progress in experimental and manufacturing development. The principle involved in the fine performances reported is the elevation of gas pressure to a point where the upward break of the usual ionization curve is pushed up to a voltage sufficiently above the operating voltage. However, it must be evident that ionization may be present in small quantities owing to surface irregularities in the gas spaces and other local causes of high stress.

My question is directed particularly to the long-time influence of this small residual ionization. Evidence of its importance are found in the data in the Faucett paper and in noticeable changes in the position of ionization curves as between Figures 8 and 9 of the paper. Mr. Shanklin directs attention to the increase and subsequent decrease of power factor caused by wax formation in Figure 7 of his paper. But even here the presence of residual ionization is indicated by the slightly greater ionization factor in the range 20 to 60 volts per mil at the end of 252 days than at the beginning. Moreover, substantial local ionization is possible without reflection in the value of over-all power factor. Indeed the latter is usually not affected until the ionization assumes such large proportions that breakdown is immediately imminent.

The authors agree that further studies and performance tests are necessary for the gas-filled cable. I venture the hope that future studies will include that of the influence of local ionization of small volume on the immediately adjacent insulation wall.

Referring further to the Faucett paper on gas-filled cable, will one of the authors please give the numerical data back of the statement on page 663, beginning of column 3? What is the over-all specific inductive capacity of the gas-filled cable as compared with that of the same cable before draining? Somewhere in these papers it is stated that comparatively little oil is lost in the draining process. It would be interesting to have the figures leading to the conclusion that the stress in the gas spaces is less than that in other types of insulation.

In the same paper it is interesting to find such very clear data indicating in Figure 13 that the approximate life to failure varies inversely as the 7.5 power of the voltage. Heretofore data on this question have been very meager. As to the dielectric strength-time behavior below one hour, the impulse tests reported indicate that toward very short time values, the curve of Figure 13 will again turn up. This would result in a curve closely similar to those for other types of insulation as reported by Montsinger and others.

K. S. Wyatt (Phelps Dodge Copper Products Company, Yonkers, N. Y.): This discussion of the three papers describing extra-high-voltage cable designs which employ compressed gas parallels the session on the same subject at the Paris conference (CIGRE) in 1939. My contribution to that discussion is on record, and my remarks then hold good today. One of these designs (compression cable) employs compressed gas external to the lead sheath merely as a mechanical means of compressing the cable on the cooling cycle to insure freedom from vacuous and gas spaces; at the other end of the scale are the two designs which employ compressed gas in the insulation itself. These three papers evidently indicate that we are entering a transition stage in extra-high-voltage cable design: the new designs, with high-pressure gas-filled insulation, are challenging the older conservative designs, based on keeping filled with oil all spaces within the cable that are not filled with solid material, namely, the oil-filled, the compression, and the Oilostatic cables. The end result will no doubt be that no one design will be employed exclusively for all conditions, that is, each of several designs will find application in a restricted field.

At the time of the Paris conference in 1939, Beaver had a semi-commerical gas-filled cable at 132 kv installed as a loop of about one mile length on the Central Electricity Board system in England with more than a year's operating experience. He had also in operation for several years a number of gas-filled cables at 33 and 66 kv. Kirsch of Berlin (AEG), and Schneeberger of Brugg (Switzerland), were talking of installing operating lines at 33 kv with thick insulation and low gas pressure and gradually feeling their way to over 100 kv by increasing the stress and gas pressure. Callenders were installing at this time about a mile of 66-kv gas-filled cable of the loose-sheath type in London. While I believe an insulation thickness of 240 mils was employed, the fact that they wished to use only 100 mils for 33 kv indicates their faith in this design. Those who adhere to the principle of filling the insulation with oil rather than with gas should not lightly pass by these new designs, for they merit careful consideration.

The authors and the Detroit Edison Company in making these investigations of the compression cable and gas-filled cables at 132 kv have performed a great service for the industry. It is only to be regretted this was not done five or ten years earlier. The paper on the compression cable makes two important contributions:

1. The studies confirm for American loading conditions and conductor sizes the considerable body of work done abroad continuously since 1926.

2. A highly important design feature has been introduced, which, I understand is due to L. I. Komives, namely, the use of three S.L. cores cabled together with short lay without binders to cushion longitudinal expansion thrusts on the joints, throwing into the discard the cumbersome steel wire armor of the European design. (Europeans like to complicate, Americans to simplify and make foolproof). This gives us a simplified design which may well be called American-type compression cable.

I should like to point out that the terminal design is that of Siemens Brothers of London; so also is the joint design, except the ferrule scheme, which is, I believe, the subject in England of an Enfield Cable Works patent but which for several reasons they did not use. The work on increased fatigue endurance of lead under nonoxidizing conditions is an extension of the work of Haigh and Jones,[1] and of H. J. Gough, of the National Physical Laboratories of London. In the paper by the same authors on gas-filled cable the use of 80 and 100 degrees centigrade power-factor measurements to detect moisture pickup of impregnated-paper tapes is due to R. C. Mildner (with T. R. Scott) who, because of his considerable work on this matter, I think should receive credit.

Figure 7 shows power factors at room temperature or below up to 0.5 per cent which appear rather high. My associates and I have manufactured and installed since 1939 four compression cables at 66 kv, the 20 and 60 degree centigrade power factors of which were as low as 0.2 per cent and never higher than 0.3 per cent.

The British manufacturers have agreed to reduce insulation thicknesses for the compression cable with a limit on maximum stress of 280 volts per mil, instead of 216 volts per mil. Even if the *SMD* cable is in future reduced 20 per cent as the authors suggest, to 560 mils, this construction will still be more bulky (see Table IV).

Gas-filled cable at the lower voltages is understandable; I find it difficult to see any advantage at 132 kv, however, either economic or technical. Consider first the materials for an *SMD*-type gas-filled versus a compression or oilostatic cable: the corro-

ion-protected steel pipe is common to both; he conductor size for the gas-filled cable ill certainly not be smaller; the insulation hickness for the gas-filled cable in the resent instance is 20 per cent greater; a ad sheath is put on all three types of cables ut is stripped off at installation for the as-filled and Oilostatic types, while in the se of the compression cable the cost of its pproximately half-thickness lead sheath ill be partially offset by the cost of striping and by the greater amount of lead in e larger-diameter gas-filled cable;* the MD cable is protected with a helical D-aped copper armor wire, as is the Oilo-atic, while the compression cable has two ur-mil copper reenforcing tapes with per bedding and protecting tapes. The MD cable therefore requires not less, but anything, more materials and processing an the compression or Oilostatic designs.

Now consider the technical merits of MD-type gas-filled cable versus compres-on or Oilostatic types: The factor of safety long-time breakdown is about 2 for *SMD* probably with gas films at atmospheric pressure). Many precautions against moisture pickup, and so forth, have to be taken during manufacture of the *SMD* cable because of the necessity for preimpregnating the paper tapes first and then applying them to the conductor in the factory atmosphere, but these are not necessary with compression or Oilostatic cable. The *D*-shaped copper armor wire is essential to the *SMD* type, not only for mechanical protection, but for carrying short-circuit currents, since there is no lead sheath to make contact with the *H*-type shielding. Not least important is the great difficulty of fault location for *SMD* cable in the absence of lead sheath.

To my mind it is quite certain that some ionization occurs at spots in the *SMD* cable during operation. Although the authors use thin paper in the conductor region to keep down the radial dimensions of the butt spaces, wafers show that such a cable after bending, pulling, and installing, will have some gas spaces of ten mils and even 20 mils radial dimensions. These being filled with

Table IV. Comparative Dimensions of High-Voltage Cables

Single Conductor 138 Kv—750,000 Circular Mils

Type	Conductor Type	Conductor Outside Diameter (Inches)	Conductor Shielding	Insulation Thickness (Mils)	Lead Sheath Thickness (Mils)	Lead Sheath Re-enforcement (Mils)	Over-all Diameter (Inches)	Long-Time Breakdown Stress (Volts Per Mil—Maximum)

imensions include a helical *D*-shaped armor wire 100 mils.

Established for the compression cable in England and in Europe; after severe load cycles.

Faucett, Komives, Collins, and Atkinson; on new cable.

compared with 5 or 6 for compression 1 probably for Oilostatic cable. Thermal istivity (insulation) for *SMD* is from 700 1,000 compared with 450 for cables com-tely filled with oil. In the event (rare, it rue), of a large hole in the pipe and loss gas pressure, *SMD* cable must be taken of service immediately, whereas with compression type, the operator has 24 rs to make repairs. During installation rainy weather or during operation the lation is exposed to contamination in *SMD* type, whereas with the compres-cable the lead sheath protects the insu-on. A large hole in the pipe might let in und water which would not affect com-ssion or Oilostatic types. Impulse ngth of gas-filled cable, similar to *SMD* e, according to Beaver, is about ten per t below, and according to R. Davis,[2] per cent below standard types (for cable le with preimpregnated paper, but gas, not oil, will certainly ionize at operating voltage. The power-factor voltage curve will not necessarily show up local ionization pockets in a long length, as Doctor Whitehead has shown. The authors state such ionization would be dangerous to their cable, although Shanklin admits such ionization occurs but says it is innocuous. However, Shanklin's ionization spaces are sealed with compound, whereas in the *SMD* cable the ionization pocket is part of a continuous gas film from conductor to sheath. Before the authors can state that no ionization goes on in an operating *SMD* cable, they should submit evidence with the magenta dye test on insulation after a year's operation. Because of this ionization, I feel there is some doubt as to the permanence of the insulation of this type of cable, and careful laboratory evidence after a five-year trial period would be helpful.

While the *SMD* cable will no doubt work satisfactorily, it seems difficult to see the reasons for choosing it in preference to the compression cable. When you strip off the lead sheath, you throw away a very considerable factor of safety against breakdown, expose the cable to contamination, leave the operating man with no alternative in the case of a large hole in the pipe but to take the cable out of service immediately and make fault location difficult, without effecting any monetary saving. If the compression-cable system, American-type, were streamlined with styrene joints and styrene terminals to eliminate compensators and with styrene sheath insulators to eliminate sheath losses, it would seem to me to offer a great deal more to the operating engineer than the gas-filled types. To quote my concluding remarks at the Paris conference, "We do not think it should be taken for granted that the gas-filled cable cannot be made workable. At present, the gas-filled cable with breakdown at only 100 to 150 kv per centimeter maximum stress hardly comes up to the oil-filled and the compression cable with breakdown at 400 kv per centimeter or over at maximum stress. If the operating engineer is to demand a gas-filled cable with the same factor of safety as the oil-filled cable or the compression cable, it means that the gas-filled cable is going to be very bulky indeed in external dimensions, and it is highly doubtful whether it can come within great distance of the compression cable economically."

In this discussion we have been interested mainly in comparing the pipe-line-type *SMD* cable with other pipe-line-type cables. Where the flexibility of the duct and manhole system is desired, the oil-filled cable may be expected to hold its own.

e saving for the Detroit seven-mile line unts to $16,400 less cost of stripping and ht, that is, probably about ten cents per foot ore.

cable made with preimpregnated paper, but ably with gas films at atmospheric pressure eference 2.

Herman Halperin (Commonwealth Edison Co., Chicago, Ill.): These three papers on cables employing gas at various pressures are of immediate practical value to some users. The people and companies behind these papers are to be congratulated. In my opinion, the selection of the type of cable to use should be based mainly on the economics involved and on matters relating to usage. By the latter, I mean not only reliability in service but also matters relating to construction, maintenance, time to make repairs, and personnel.

The first detailed discussion will be on the paper by Mr. Shanklin. His article states that to date experience indicates that the low-pressure gas-filled cable is satisfactory from a technical standpoint. On the other hand, solid-type cables operating at 12 kv, 22 kv, and 33 kv are giving satisfactory service. Aging tests, for example, on shielded three-conductor 12-kv cable in Chicago show that there is no appreciable change in ionization nor power factor after severe testing—in other words, it is perfectly stable. We have a low rate of troubles in service, and in any event we must expect, in laying out designs for service, that with any kind of cable failures may occur. If a man drives a steel point into a cable, then one will get a signal that there is trouble on a gas-filled cable, but anyhow the line will be out, and one will get the signal through the regular manner.

Another point with us is that we use parts of existing 12-kv lines to make up a portion of a new line in many cases, and the use of the solid type simplifies our activities in addition to saving money.

In connection with single-conductor cables, I wonder what trouble might occur because of oil slugs, even if the gas connections are paralleled, when there are severe differences in line profile. These differences will affect all three phases equally.

The power factor–temperature characteristic of this type of cable appears to be less favorable than that of solid-type or oil-filled cable. Figures 6 and 8 of the paper indicate that even after stabilization the power factors at 80 degrees centigrade are two to three per cent as compared with about 0.4 or 0.5 per cent for new solid-type or oil-filled cable.

It is surprising that neither grading of the tape thickness nor conductor shielding produced any effect in test results. Is it possible that by making these changes in cable construction other unknown variables were introduced which offset the expected effects?

From creep tests made by Professor Moore at the University of Illinois under the sponsorship of Utilities Research Commission, it appears that Asarco cable lead should be satisfactory for 225–250 pounds per square inch. Tests in a dummy manhole in Chicago indicate that Asarco cable lead containing about 0.018 per cent calcium will withstand bending in manholes at least as well as ordinary lead.

In my discussion of the two papers by Faucett, Komives, Collins, and Atkinson, I refer first to the commercial installation of the gas-filled cable.

One question of considerable interest concerns the thermal characteristics of these cables. For a given load how does the temperature rise from ambient to conductor compare for these cables and solid or oil-filled cables on the basis of one line or two lines? Also, what maximum temperatures are considered permissible for the gas-filled and compression cables for normal and emergency operation?

The thermal resistivities of soil shown in Figure 4 appear to be lower than those reported by others. More data would be of interest. Since the ionization point is a function of the pressure, it would be of interest to learn what variations in pressure are expected in normal operation.

Figures 14 and 15 indicate relatively good impulse strength for the gas-filled cable which, however, had conductor shielding as mentioned by the authors. In other reports based on the Detroit tests, Mr. Komives has shown that the thoroughness of impregnation and smoothness of conductor surface had marked effects on the impulse strength. In 1938 G. B. McCabe presented data before the Edison Electric Institute showing that drained impregnated paper had only 60 to 70 per cent of the impulse strength of well-impregnated paper. These five types of cable in the figures cover a considerable range in degree of impregnation of the insulation and should, we believe, show some differences in impulse strength. This point is important, because the thickness of insulation used in some of these high-voltage cables is determined largely by the impulse strength.

No data are given on the effect of drainage on impulse strength. That drainage does have an effect on the characteristics of the cable is shown by the fact that drainage reduced the ionization point from 140 to 130 kv and reduced the breakdown strength by ten per cent. What are the possibilities that, through the years of service, considerable draining of compound may occur to cause more severe reduction in quality?

Regarding high voltage–time 60-cycle tests on new cable, it seems from our data that the oil-filled cable is somewhat superior to the gas-filled cable, and the unit strength of the oil-filled insulation will not change in service. This disagrees with conclusion 5 but does not affect particularly the installation of commercial gas-filled cable which has 20 per cent more insulation than is required for oil-filled cable.

It is of interest that failures occurred in the region of wide interturn gaps. May this be due to the field distortion caused by combination of solid and gaseous dielectrics or due to the greater probability of radial lining up of interturn gaps?

The connector used in the joints with a wall thickness equal to the diameter of the strands in the outer layer of the cable conductor is an improvement over present practice. Although we have reduced our wall thickness, still we have been using connectors which are unnecessarily heavy.

How much time is it expected will be required to make repairs in case of failure on such installations in steel pipe?

The half-round copper wire spiraled over the insulation of each conductor will have a voltage induced in it which might cause minute sparks to the steel pipe. Have any test data or calculations been obtained regarding these voltages and their effects?

Regarding the other article, drainage of compound may also be a factor in the compression cable. If cracks should occur in the sheath, there would be no warnings telling the operator that compound is draining from the cable into the pipe. This is important, because loss of pressure in the pipe is not considered hazardous so long as the cable is at elevated temperature. However, if gas has entered the insulation under such conditions, then such operation might produce electric breakdown. The further information on the sample with perforated sheath will be, therefore, of considerable interest.

It should be understood that a lot of questions do not necessarily deprecate a development when it is quite new, as are essentially the matters covered in these three papers.

F. W. Main (The Enfield Cable Works Co., Ltd., Brimsdown, Enfield, Middlesex, England): I am pleased to have the opportunity of contributing to the discussion on the three cable papers read at the Chicago summer convention. I have not had any direct contact with experimental work or experience of any installations of gas-filled cable, as my company has been interested in the development, supply, and successful operation of the compression cable in which a pressure medium, usually gas, although not in actual contact with the dielectric, compresses the dielectric through the medium of the lead sheath which acts as a flexing diaphragm.

The compression cable was formerly known as the pressure cable, being the first cable in commercial use employing gas under pressure; later, cables employing gas, either in the dielectric or in direct contact therewith, were constructed, and the term pressure cable was applied indiscriminately to all cables employing gas, and, therefore, in 1940 the title of compression cable was given to the diaphragm cable to prevent confusion.

I would like to express admiration for the development work carried out in America in connection with the compression and gas-filled cables as indicated by the papers read, and I would also pay tribute to the earlier work published in 1939.

The electrical research work in connection with gas-filled cables has been necessarily involved because of the introduction of gas into the active dielectric hitherto normally consisting only of paper and impregnating oil or compound. In the compression cable, however, no elaborate electrical research has been necessary, as in general terms it is essentially a mass-impregnated straight-type cable. Any developments in the electrical sphere have not been peculiar to the compression cable but have been toward improving, by design and shop processes, features and characteristics that can be, and have been, embodied in general impregnated high-voltage and super-voltage cables.

In the paper by Faucett, Komives, Collins, and Atkinson on the 120-kv compression cable, it is stated that the *HSO* construction has been discontinued abroad. This is not quite correct; although the original compression cable installation, which has been in successful operation in Great Britain since 1932, was of the *HSO* construction, and the subsequent cables in Europe, and more recently in Great Britain, have been of the *HSL* pattern, a cable is being manufactured at the present time of the *HSO* type. This cable is not being drawn into a pipe as in the case of the original British installation, as it is a self-contained type, an outer lead sheath acting as the container for the pressure gas.

As the lead-sheath diaphragm in contact with the dielectric breathes in sympathy with the fluctuations of cable temperature, it was considered by some engineers that the lead sheaths of an *SL* three-core cable, being smaller in diameter than the sheath of a three-core screened cable, would be more satisfactory; any fears, however, of a sound lead sheath not giving satisfaction in service have been dispelled by tests made in Europe and now confirmed by experiments carried out in America as described in the paper. The *SL* type has also met with favor, as jointing in some respects is simplified, but this is not peculiar to compression cables.

The relative merits of the pipe-line and self-contained types of compression cable cannot be dismissed in a sentence; local conditions or even prejudice may affect a decision. Obviously, the pipe-line type affords the greater mechanical protection, and the cable can be manufactured in longer lengths; the pipe-line can be installed at a convenient time and the cable drawn in subsequently; the compression cable can be drawn into an existing pipe provided the line in gastight, and, further, if there be sufficient clearance in an existing pipe-line, the cable in position can be

withdrawn and a larger cable substituted to give increased capacity. In Great Britain only one of the compression cable installations is of the pipe-line type.

In the paper reference is made to an additional lead sheath to protect the reinforcement tapes of the self-contained cable from corrosion; this additional sheath is, however, not necessary, as there is a number of finishes available that can be used to give further protection and to render the cable impervious to moisture. For this purpose, unless the purchaser specifies an additional lead sheath, we use a sandwich finish which consists of at least two layers of nonfibrous material such as a rubber-bitumen compound reinforced between the layers with a fabric tape.

Mention is made of a spiral wire between the diaphragm lead and the gas-retaining lead of a self-contained compression cable to ensure a free channel for the pressure gas; this we have found is unnecessary, as we employ a circular gas-retaining sheath over a noncircular lead-sheath diaphragm for both three-core screened and single-core types which automatically provides the necessary space.

It is noted that concrete was applied around the pipe in the trench along the armored section of the experimental line. I assume that there is no significance in applying concrete in this particular section.

The investigation into longitudinal movement, comparing the effect of bound and unbound cores, we find is very interesting, and we would welcome more details.

In the paragraph dealing with cable design, mention is made of impregnated jute fillers laid up with the lead-sheathed cores: we have not found the use of fillers necessary.

We are interested to note that tight lead sleeves have been used successfully in joints, whereas we have favored fluted brass or copper sleeves. We shall be interested to have some notes on the effect of fatigue tests taken, especially in the proximity of the wipes.

With reference to terminals, we have given some attention to the use of a Bakelite tube inside the porcelain as discussed in the paper, but we concluded that the complications involved did not warrant the benefits obtained.

Details of load cycles are given in the paragraph headed "Field Test," but whereas a figure for the copper temperature is given in the paper for the 120-kv gas-filled cable, no figure is given for the compression cable. We anticipate that this would be a lower figure, however, because of the lower thermal resistance of the compression cable compared to that of the gas-filled cable.

With regard to the question of power factor, the figure we obtained for cables manufactured in Great Britain is in the neighborhood of 0.0028–0.0030 at 20 degrees centigrade compared to 0.0040–0.0043 as shown in Figure 7 of the paper.

Coming to the paper on the 120-kv-high-pressure gas-filled cable, there are a number of causes suggested as being contributory to the satisfactory solution of the gas-filled cable. Of the seven causes mentioned, surely five at least have been developed by various cable manufacturers for the improvement of super-voltage cables generally and are, therefore, not peculiar to this one type.

It would appear that in the types of gas-filled cable described too much emphasis is placed on the quality of the compound used to impregnate the paper as, by virtue of the lower permittivity in the gas layers, the stress in the impregnating paper is somewhat relieved through higher stresses being thrown into the gas space.

We shall be interested to have more details of the saturant used. A viscosity figure of 3,000 is given for the compound used for preimpregnating the paper for the gas-filled cable; we wonder whether this figure should be 300. It is noted that in Mr. Shanklin's paper the optimum viscosity of compound used is given as 100; we use a mineral-oil-base compound having a viscosity figure of the order of 285 Saybolt.

In Figures 14 and 15 impulse strength values of the *SMD* cables are given and compared with results of certain other cables. One questions whether the other cables were manufactured during the same period as the *SMD* cable and whether the same improved constructional features were common to all, for it does not seem reasonable to anticipate that a dielectric containing gas, even if under pressure and having an uneven stress curve through the whole dielectric, will have impulse values higher than the more homogeneous oil-filled or compression cable, or even a new well-made solid cable.

It is not surprising to learn that the factory shops, where the gas-filled-cable cores are paper-lapped and laid up, are controlled for humidity. This appears very necessary as the paper is preimpregnated, but these precautions are not essential in the manufacture of compression cable.

The lead sheath of the *SMD* cable and the other gas-filled cables is removed on site, and it is found that depreciation takes place in the cable during the process; this is to be expected, however, as it is certainly a delicate operation and must discount to some extent meticulous care taken during manufacture.

In the paper it is stated that the minimum safe-operating gas pressure for the cable is approximately 100 pounds per square inch; yet earlier, it is stated that the electrical tests which, of course, would be at a voltage higher than the working voltage, should be applied to the cable with only 30 pounds per square inch of nitrogen pressure.

Reference is made in the paper to tests for radial power factor and results are given in Figure 10. There is a difference, however, in the radial power-factor curve for mass-impregnated paper as against a true curve for gas-filled cable; the curve given for gas-filled cable only shows power factor in the papers and gives no indication of the effect of the gas space on the shape of the curve through the whole dielectric. One wonders what the shape of the radial power-factor curve would be if the humidity in the shops during manufacture were not controlled.

Unless we misinterpret the authors' statements, we are unable to agree with the inferences given as drawn from Figure 8. The stress in the paper of the insulation is reduced only because the distribution of stress throughout the dielectric is distorted since the permittivity of the gas spaces is of the order of one third of the value of the impregnated paper, the stress in the spaces being correspondingly higher than that in the paper. Therefore, the electrical strength of the impregnated paper cannot be used to full advantage; otherwise the gas spaces would be overstressed, and destructive ionization result.

One can appreciate the usefulness of the low-pressure gas-filled cable, as described in the paper by Mr. Shanklin, for voltages between 30 and 50 kv, where a high breakdown stress is not so necessary as with the higher voltages. As the gas is only at a low pressure, a reinforcement is not necessary, and consequently there is a reduction in cost and diameter, the latter being important in situations where space is at a premium, but the position is not so clear for higher-voltage cables.

It is very surprising to note that, after the cable has been drained, the finished product was almost as well filled as a solid type cable. This is contrary to our own experience.

The authors express doubt as to the mechanical soundness of employing a reinforced lead sheath to contain a gas pressure of 200 pounds per square inch. This, however, is standard practice in England for self-contained compression cable and has given complete satisfaction.

A statement made concerning the effect upon power factor of exposure to air can be appreciated.

While the difficulties of stripping the lead sheath from a gas-filled cable on site as it is drawn into the steel pipe line have been somewhat overcome, it would seem more logical to draw a compression cable into the pipe line and avoid this stripping operation with attendant risks, and at the best, a certain amount of depreciation. It is admitted that a compression cable has a higher factor of safety, and, in the event of the lead sheath diaphragm of the compression cable being damaged, the cable would then automatically become practically a gas-filled cable without the costly complications involved during the installation of such cables.

G. B. Shanklin: In slightly different forms the same two questions have been raised by Halperin, Komives, Del Mar, and Hickernell. In effect, these two questions are:

(a). **Why does low-pressure gas-filled cable show more increase in dielectric power factor on overvoltage load-cycle tests than does the best modern type of solid cable, and what significance does this have as related to stability in service?**

(b). **Why is average stress used rather than maximum stress in the design of mass-impregnated gas-filled cable, and why do strand shielding and extra thin paper tape appear to show no appreciable benefit on comparative load-cycle tests?**

Initially and in the absence of ionization the dielectric power factor of both types is the same. The increased power factor of low-pressure gas-filled cable on load-cycle aging tests is merely due to the fact that this type of cable has a greater volume of gas space to be ionized, and the signs of ionization, accordingly, show up more clearly when the cable is subjected to an overvoltage stress where severe ionization can take place. This has no significance at all as related to stability in service. The chief goal of service stability is uniform control of ionization and prevention of a cumulative action. Gas-filled cable gives this through pressure control. That is why laboratory tests on short lengths can be made to simulate closely service conditions

and furnish a reliable yardstick for design work. Solid-type cable lacks this uniformity and close control under service conditions, requiring heavier wall of insulation as a protection against localized cumulative weaknesses.

Strand shielding is, in effect, a method of carrying stress grading of cable insulation a step further, to better equalize stressing throughout the insulation wall. It is effective only when the inner layers of insulation are of equal or lesser strength than the outer layers. It is not effective when the inner layers are somewhat stronger than the outer. The maximum-stress theory is governed by the same conditions and does not hold when the successive layers of insulation in an outward direction are of decreasing strength.

When a mass-impregnated gas-filled cable is drained of surplus compound, the laws of capillary attraction are followed. The outer layers of insulation are drained the most, and the largest void spaces occur here. The inner layers of insulation are drained the least, and the void spaces in this location are of minimum size. As a result, ionization either starts in the outer layers first or occurs uniformly throughout the whole insulation wall. It never concentrates in the inner layers alone.

To sum the matter up, mass-impregnated gas-filled cable already has, in effect, automatic grading that counterbalances the higher stress near the conductor. For this reason, any further attempt to grade, such as by use of strand shielding or extra thin paper in the inner zone, does not accomplish so much as would be expected. The use of average stress rather than maximum stress in design work is explained on the same basis.

It should be emphasized that these conditions do not hold for preimpregnated gas-filled cable, where the region near the conductor is the critical zone, and means of improving grading are necessary.

In comparing solid and gas-filled types of cable Mr. Halperin stated that if a man drove a steel point into a cable you would get a signal in the regular manner with either type. He means, of course, that this would happen if the damage were sufficient to immediately cause short circuit. A few months ago a man did drive a steel point into a gas-filled cable, but only the sheath and outer wrappings were damaged. After the gas-pressure relay signal, the damage was located and repaired within a short time without service interference. Service records show that the large majority of failures in solid-type cable are due to sheath damage or leakage from various causes. It is reasonable to assume that gas pressure supervision will largely eliminate such interruptions to service and, so far, field experience has confirmed this.

Mr. Del Mar expresses the belief that the highest possible viscosity of impregnating compound is desirable. In the case of preimpregnated gas-filled cable I readily agree. This type of cable would not work well without extreme viscosity of impregnating compound. In the case of mass-impregnated gas-filled cable some years of experience has demonstrated that lesser viscosity of impregnating compound gives the best results. It is important to obtain the best possible initial impregnation of the heavy wall of insulation. Drainage of surplus compound and capillary balance will then give the right degree of automatic grading, as previously described. These results cannot be accomplished so well with extreme viscosity of compound.

Referring to the medium-pressure system, Mr. Komives is correct in stating that high creep-strength sheath is a new development and needs to be proved. We can only say that this work is progressing well and looks promising. Double-reinforced sheath at 30 pounds per square inch, however, is proved thoroughly in service, and with present quality of sheath the pressure can be increased, provided it is within safe strength limits of the lead wipes. A sudden jump to 200 pounds per square inch, as some propose, does seem, however, to be out of proportion.

Dr. Whitehead asks about residual ionization in gas-filled cable. All of the evidence we have been able to obtain indicates there is none of noticeable effect. Long-time load-cycle tests are always run at an overvoltage sufficiently high to produce pronounced ionization and are of no direct value in clearing up this point. A study of the charts will show that, at each voltage step before ultimate breakdown, ionization is extinguished, and the cable stabilizes because of self-healing action. This would indicate that ionization in this cable is retrogressive and that residual or incipient ionization cannot be sustained. Actual field experience is more conclusive. Gas-filled cable operates at a voltage stress only a little below the ionization-starting voltage stress, as represented in Figure 5 of my paper. This must mean that during switching surges and other overvoltage transients there are at least brief flashes of ionization discharge in the cable. These discharges must be immediately extinguished or, if sustained, must be of negligible effect, because no evidence of ionization deterioration has yet been found in service.

Whether or not Doctor Wiseman's belief that pipe cable systems are not limited to open ground but are comparable to the usual flexible duct system under paved streets is something that will have to be proved by experience. It all depends upon how many leaks are going to occur in the pipe systems and how much tearing up of the streets will be necessary in locating and repairing them. If the means being taken to prevent such trouble succeed, then Dr. Wiseman is correct.

His claim that, for a given amount of power to be transmitted, Oilostatic cable should have a conductor size equal to or smaller than that required for single-conductor oil-filled cable in ducts is based on his well-known method of calculating current-carrying capacity. To accomplish these results Doctor Wiseman uses a soil thermal resistivity of 80 net in his calculations for Oilostatic cable. Most of the rest of us use the more conservative and generally accepted standard value of 120 net, corresponding to a moisture content in the order of five to eight per cent. Only a porous soil completely saturated with water could show a thermal resistivity as low as 80 net. It stands to reason, then, that the relative carrying capacities of the two types of cable are not directly comparable on Dr. Wiseman's basis.

I. T. Faucett, L. I. Komives, H. W. Collins, and R. W. Atkinson: The authors are very much pleased with the interest shown in these two papers and wish to thank the many engineers who have submitted discussions. For the most part these discussions either contribute or ask for additional information. A few are somewhat critical of one or the other of the two types of cable which we have described. Mr. Wyatt wonders why preference could have been denied the compression cable, and Mr. Shanklin fails to see how there could have been any doubt in selecting the gas-pressure cable. It is significant that each of these discussers has shown so much confidence in the type of cable of which he has previously been best informed. Our own very complete investigation in the laboratory and in the field of *both* types gives us confidence in *both* and indicates that satisfactory results are to be expected from either.

In his approach to the high gas-pressure cable Mr. Shanklin has a different viewpoint, concerning several aspects, than have the writers. Mr. Del Mar has summarized these differences very conveniently and has also declared his agreement with the writers in most cases. Mr. Del Mar's tabulation makes a very convenient basis for this discussion.

The first two points may be discussed together. Shanklin uses a much lower-viscosity saturant than the writers and expresses concern about the exposure to the air occasioned by the use of preimpregnated paper. He also states that he has tried high-viscosity compound and has found it apparently inferior. It seems that the difference between Shanklin's results and ours is not wholly in the viscosity. For instance, Figure 6 in his paper, which he considers typical, shows that the power factor of his cable below the ionization voltage at 80 degrees centigrade increases rather quickly to three per cent and then drops to around two per cent, remaining at that value for the duration of the test. On the other hand, the power factor of our insulation is less than one half of one per cent from 40 to 100 degrees centigrade and has shown no change as a result of any of the testing. Mr. Shanklin's discouraging results tend to confirm our contention that our very good results are due to other good qualities in the saturant in addition to its high viscosity.

Mr. Shanklin grants theoretical advantages in the use of thin tape but says that thin tape is more expensive and difficult to apply, tends to wrinkle more, and will not withstand bending well. He apparently concludes that these difficulties cannot be overcome. It seems likely that this is the reason for his failure to obtain good results with thin tape. In our cables we overcame these difficulties by combining a number of means to accomplish that end. We used a superdense paper that had not been previously available in such thin tape. Because of the great stiffness and smoothness of this paper, it slides instead of wrinkling during bending of the cable. This sliding is also facilitated by the lubrication given by the presaturation, as well as by use of proper amount of tension during taping. Finally, the amount of thin paper was limited to that required for electrical reasons. In the region of lower stress, where the mechanical requirements are more severe, successively

thicker tapes were used. Not merely were we able to increase the electrical strength of this type of cable with such tape, but we have accomplished a similar result in other types. Beaver has also accomplished important gains with thin tapes of graded thickness, even without the special superdense paper, but he too has had the benefit of presaturation. The experimental high-stress 132-kv cable with only 386 mils of insulation which we manufactured for the Commonwealth Edison Company in 1929 and which has been reported on by Mr. Halperin[1] was made with three-mil paper tapes. This cable showed an exceptionally fine record for the $8^1/_2$ years net time of testing after which impulse-strength measurements were made on the cable by the Detroit Edison Company. Maximum impulse stress values of 3,250 and 3,450 volts per mil were obtained with corresponding average stress values of 1,890 and 2,010 volts per mil.

The case for strand shielding is similar to that for tape thickness. For many years the theoretical advantages have been recognized. Beaver and others in Europe have found practical advantage for various types of cable. In two papers in 1940 we pointed out important advantages of strand shielding in solid-type cables and we have been able to demonstrate important values in other types. It may be remarked that it is not improbable that the gain occurs more from the shielding from stress of the nonsolid dielectric between strands than from the reduction of stress that is discussed in the classical theories. At any rate the remarkably high dielectric strength for surges which has been obtained on shielded high-gas-pressure cable seems explainable only if the strand shielding is credited with a very substantial benefit.

Mr. Shanklin would like to know, on purely technical grounds, why preimpregnated paper was selected in preference to mass-impregnated paper. The answer is simply that a very high-viscosity compound was essential in order to prevent migration, and the only means by which it was possible to impregnate the tapes thoroughly with such a compound was by the preimpregnation of the tapes. Thus, from the very important standpoint of compound migration, this produces a cable far superior to that which can be achieved with the lower-viscosity compound which must be used with mass impregnation. At the same time superior electrical properties—low power factor and high stability—have been obtained by the use of this compound as shown by the test data reported in the paper.

Mr. Shanklin offers his own answer to his above question by saying: "A comparison of initial ionization-starting voltage stress as a function of gas pressure tells the whole story," and states that such a comparison is given in Figure 6 of his discussion. This comparison is of sufficient interest to merit careful study. In his present paper, Mr. Shanklin says that additional data obtained since the first paper allow a more accurate construction of this curve than before, and it is noted that the values now given are over ten per cent higher than in the old curve. Mr. Shanklin gives all his data in terms of average stress. As recalled to us by Mr. Del Mar, Mr. Shanklin grants: "It is better to deal with maximum voltage stress than average," but pleads the greater convenience of the use of average stress. It is allowable to serve this convenience only when it does not lead one astray by provoking comparisons under conditions where the ratio of maximum and average stress differ so greatly as to distort the comparison. Since Mr. Shanklin has described curve *A* in his paper just referred to as "a representative average of all tests on single- and three-conductor gas-pressure cable," we may suppose that there was no distortion of the comparisons of his own cable by his basis of comparison. In order, therefore, to compare his tests with others on the basis of actual maximum stress, we have determined the actual maximum stresses for one of the cables which he used and on which he has given dimensions. This cable is a single conductor 400,000-circular-mil stranded conductor with one-half-inch hollow core, 300 mils insulation, the stress being calculated by application of the ordinary logarithmic formula from the average stress as given on curve *A*. Likewise the maximum stress was determined for the cable represented by curve *B*. Thus it is found that, at 200 pounds pressure—where Mr. Shanklin states that there is practically no difference between the two types—the *maximum* stress for initial ionization is 300 volts per mil for our preimpregnated cable, as compared with only 236 volts per mil for his mass-impregnated cable. In other words, a 27 per cent higher ionization voltage for preimpregnated paper certainly justifies its selection.

This difference is emphasized still more when it is remembered that the preimpregnated cable on which he has made the comparison was drained after being maintained at a temperature of 100 degrees centigrade throughout its cross section for 65 days in an inverted *U* position. His 1939 paper indicates that curve *A* was based on drainage from load cycles reaching a maximum temperature of about 60 degrees centigrade "for a number of days." Thus, if we take Mr. Shanklin's suggested comparison of ionization tests on a comparable basis of dimensions and conditions, the results show another very effective reason for choosing the type of insulation we did.

It is rather important to discuss certain comments on test methods and significance of tests as made by Mr. Shanklin. He indicates that we should have supplied test data showing load-cycle endurance runs of the type which he has used and which he has found to stabilize his cable. However, as will be shown, the tests and criteria which we have reported have been much more severe and searching than those used by Mr. Shanklin. Since Mr. Shanklin's data for high gas pressure is limited to initial ionization measurements, we must perforce analyze his comments in the light of his data obtained at low pressure. He mentions a certain cable showing little ionization at 77 volts per mil which he tested at various voltages from 85 volts per mil to 120 volts per mil. The cable "stabilized" at each successive step except the last where "the stress was too high for the same kind of stabilization to take place, and failure occurred in a few days." He names an operating stress of 65 volts per mil for this cable and believes that the experience with similar cable operating at this stress indicates "that there is a good margin of safety and some latitude for increasing present working voltage stress." Moreover, as pointed out by Mr. Del Mar, he makes no distinction between cables having different ratios of maximum to average stress, and thus his recommendation, based on average stress, will lead to operation at considerably higher maximum stress on some other cables than on this one cable. In any event the average operating stress which he recommends is 54 per cent of that at which his stabilized cable sample breaks down "in a few days." The cable at Detroit operates at 70 kv, or only 45 per cent of the 155 kv which is withstood indefinitely by most of the samples, or about 50 per cent of the 140 kv required to break down in 120 hours the sample drained at 100 degrees centigrade for 44 days. This serves to emphasize the effectiveness of the test procedure which we have used and to show that it is even more searching than his and that the rating of cable in this way is considerably more conservative than would be obtained by following his program and criteria.

Mr. Shanklin states in reference to gas pressure cable, "We started initial development work in 1932, the principles of which are described in United States patent 1,991,230 filed in July 1933." Our own much earlier work in this connection was disclosed in United States patents 1,524,124, 1,541,937, and 1,651,590 the first of which was filed in 1920 and granted in 1925. These patents have been recognized as basic for gas-filled cable (see letter by P. V. Hunter in *The Electrician* December 21, 1934 and article by C. Turnbull in *Electrical Review*, page 425, 1936).

Mr. Del Mar suggests that the high-pressure gas-filled pipe-type cable system is virtually the Oilostatic system without the oil and oil-pressure accessories and therefore should be interesting from a first-cost standpoint. We feel that the *maintenance* cost on this type of cable will be equally interesting.

In Mr. Del Mar's discussion on compression-type cable it is intimated that Detroit had taken on the combined difficulties of the pipe-type cable and those of the duct-type cable, whereas actually, the commercial line as installed in Detroit cannot have any of the more common troubles of the duct-type cables, since these cables have no lead sheath. Even though the compression-type cable with its lead sheath were used, the pipe would eliminate the major causes for faults occurring on duct-type cable, namely, external mechanical damage, sheath failures in manholes and at duct edges caused by cable movement, and failure from sheath corrosion.

Del Mar and Hickernell have commented on our statement that the power-factor tests on the installed cable, which were not made above 28 degrees centigrade "show no evidence of deterioration." We quite agree that tests at this temperature are not sensitive to some types of changes that are observable in tests made at higher temperatures. However, some types of change are shown more readily at low temperature than high, and, moreover, if there are changes at high temperatures, these are usually accompanied, as admitted by these discussers, by significant changes at lower temperature. Moreover, abundant information on the stability of the high-temperature power factor

is given by the laboratory tests which are reported. Figure 10 shows that there is no change in the radial power factor at 80 degrees centigrade after aging for 113 days at a temperature of 100 degrees centigrade throughout the cable cross section. At the time of this writing, there is still no change in the over-all 100 degree centigrade power factor after aging for over nine months at 100 degrees centigrade. Another sample reported was tested at 75 degrees centigrade throughout its cross section with a total time of heating of 1,250 hours and with voltage applied for 530 of these hours of from 1.7 to 2.4 times the rated voltage, and it showed the power factor to be constant throughout the test at a value of 0.3 per cent. The paper by C. J. Beaver and E. O. Davey gives data on cyclic aging tests made on this type of insulation and reports that no sign of ionization nor deterioration could be detected from such tests. The field measurements serve thus as a helpful supplement to the ample data showing the high stability of this cable. These data on the field in-

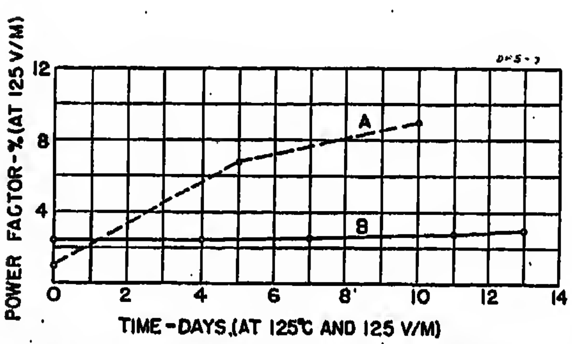

Figure 7. Power-factor aging characteristics metallic shielded conductor versus CB shielded conductor

A—*CB* cable model data from Rosch[2]

B—Commercial three-conductor cable with metal-backed paper conductor shield

stallation will ultimately be supplemented by measurements at high temperature.

Mr. Hickernell makes the comment that all that is needed to make this high-pressure gas-filled cable a truly up-to-date design would be to incorporate Rosch's carbon-black protection. Rosch has urged the value of carbon black as a means of maintaining original low power factor. However, the test data reported for the *SMD* cable show remarkable stability. Original low values of power factor have been maintained throughout the various long-time high-stress and high-temperature tests, and including long-time high-temperature tests conducted at stresses as high as 250 volts per mil. This may be compared with the data for cable "protected with carbon-black paper" shown in curve *A*, Figure 7, taken from Figure 3 in Rosch's paper.[2] This cable during ten days' testing at 125 degrees centigrade at a stress of 125 volts per mil increased in power factor at 125 degrees centigrade from the very low value of about one per cent at the beginning to about nine per cent after ten days. This may be compared with curve *B* of Figure 1 which shows data which we have obtained on solid-type cable with metallized paper shielding maintained at 125 degrees centigrade and 125 volts per mil for 13 days. It will be noted that although the initial power factor of this sample was nearly 2.5 per cent at 125 degrees centigrade, the power factor after 13 days was less than three per cent, showing incomparably greater stability than Rosch's carbon-black sample.

In regard to impulse strength, Mr. Hickernell refers to the data in the reports by L. I. Komives and G. B. McCabe and makes the statement that, "These data indicate the highest impulse strength was obtained with type-*CB* construction." There is nothing in either of these two reports that would justify any such statement. In Mr. Komives' report the only type of strand shielding tested was that having *CB* construction, and therefore it is impossible to make any comparison between it and cable having metallized-paper conductor shielding. In Mr. McCabe's Edison Electric Institute report, the average values reported did show a slight advantage in favor of *CB*-type cable, 1,870 volts per mil average stress as against 1,833 volts per mil for cable using this type of metallized paper. However, Mr. Hickernell evidently overlooks the fact that the value of 1,833 volts per mil is lower, because it includes terminal failures (not cable failures) on two of the three conductors tested and also overlooks the author's definite statement to this effect, that "It should be borne in mind that since conductors 1 and 2 failed in the terminals, the surge strength of the insulation of these two conductors was somewhat higher than the recorded values probably equal to or higher than the maximum value of average stress attained in same 18" (with *CB* tape).

Another point of superiority of the metallized tape used for insulation shielding is that it proved to be a very effective moisture barrier. Two samples of unsheathed *SMD* cable exposed to humid atmosphere for approximately two months showed no increase in moisture content of the insulation. The physical properties of carbon black are such that it is improbable that it would provide this desirable moisture barrier as does the metallized tapes.

It is difficult to understand the basis for conclusions drawn by Mr. Hickernell from the report of F. Farmer on cable in vertical runs. The only comparison we can draw concerning compounds in this report is that the compounds which showed low migration had higher viscosities at all temperatures than the compounds which gave trouble from migration. In this reference it should be noted that those cables made in 1915 to 1920 and impregnated with a so-called nonmigrating compound consisting of petroleum grease and rosin showed extremely low migration, despite the fact that several of them carried 1918 war loads which would produce temperatures in excess of the melting point of about 52–53 degrees centigrade for such compounds. The Saybolt Universal viscosity of such nonmigrating compound is less than 1,500 seconds at 60 degrees centigrade, whereas the viscosity of *SMD* compound is 40,000 seconds at 60 degrees centigrade. At the maximum normal operating temperature of 70 degrees centigrade, the *SMD* compound has a viscosity of approximately 20,000 seconds, which is in the range that the usual solid-type cable oils will have at temperatures of 20 degrees centigrade or below. Thus, there is no more reason to worry about migration in this gas-filled cable at 70 degrees centigrade than there would be with solid type cable at 20 degrees centigrade.

Mr. Halperin has asked what temperatures are considered permissible for the gas-filled and compression cables. It is recommended that the same permissible temperatures that have been adopted for oil-filled cable be used for these two types of cable. In regard to variation in gas pressure, the maximum range of gas pressure caused by temperature changes in operation will occur between the conditions of a sustained maximum load on the feeder at the time of maximum earth temperature and the removal of the feeder from service for an appreciable period at the time of minimum earth temperature. If this minimum pressure is made 200 pounds per square inch, the maximum pressure will be about 230 pounds per square inch for the *SMD* installation. The more probable range of pressure that will occur in normal operation will be considerably less than the above maximum. Mr. Halperin draws attention to the fact that the five types of cable included in Figures 14 and 15 cover a considerable range in degree of impregnation and should therefore show some differences in impulse strength. The data presented in these figures, except for the *SMD* type, are not new but have been taken from published data. The high values of impulse strength for the *SMD*-type insulation tested under high gas pressure, as compared to previous measurements on drained cable, may be attributed in part to the high dielectric strength of gas at this high pressure. As stated by Mr. Shanklin in his discussion, "the electrical strength of nitrogen gas at 200 pounds pressure is almost as great as that of the solid insulation." Also it is very probable that conductor shielding and the thin graded tapes contributed in securing these high impulse values for the *SMD*-type cable. We are not familiar with the data Mr. Halperin has which disagrees with conclusion 5 and wonder if it does not apply to a different type of insulation than the *SMD*-type using high gas pressure, graded tapes, and strand shielding, to which conclusion 5 is intended to apply. Test failures occurring in the regions of wide interturn gaps are probably due to both reasons given by Mr. Halperin. The half-round copper wire is in direct contact with the steel pipe and is solidly grounded to the pipe at all joints so that no appreciable voltage will exist between turns or from the wire to pipe, and there will be no tendency for sparking.

Mr. Wyatt refers to Figure 7 in the compressor-cable paper and states that the values of "power factors at room temperature or below up to 0.5 per cent appear rather high." He goes on to speak of having made compression cables "the 20 degrees centigrade and 60 degrees centigrade power factors of which were as low as 0.20 per cent and never higher than 0.30 per cent." We feel sure that Mr. Wyatt has overlooked the fact that with impregnated paper of very low loss, the temperature for minimum power factor is well above room temperature and that the power factor at temperatures *well below* room temperatures as given in Figure 7 will be greater than at ordinary room temperatures.

We know of no lower accurately determined values of power factor on paper cable than those reported in Doctor Whitehead's

extended series of carefully controlled measurements of cable insulation. Thus, though Mr. Wyatt states that none of his values exceeded 0.30 per cent, none of Doctor Whitehead's values at 30 degrees centigrade or below are as *low* as 0.30 per cent. Doctor Whitehead's lowest values were obtained with oil of extremely low power factor, the oil being very fluid and the paper of low specific gravity as compared with usual cable practice. It seems likely from various collateral information, that the lowest of Doctor Whitehead's values represent a condition substantially as low as have been obtained with cable paper and any saturant. We suspect that, if Mr. Wyatt will investigate carefully, he will find that the values he mentions apply not at 20 degrees centigrade and below but at the higher temperature of 60 degrees centigrade or more, where the power factor should be considerably lower than 20 degrees centigrade.

From Mr. Wyatt's statement that: "Although the authors use thin paper in the conductor region to keep down butt spaces, wafers show that such a cable, after bending, pulling, and installing, will have some gas spaces of 18 mils and even 20 mils radial dimensions", it is not clear whether this is a deduction or whether he has prepared or secured a wafer that seems to indicate that conclusion. Also it seems to imply definitely that such spaces are to be expected even in the region of thin tape. We have made a good many wafers and believe that this statement is entirely unrepresentative of the cable that is installed in the commercial line at Detroit. Our wafers, made from samples of this cable, show that the maximum spaces that were found are quite closely equal to the tape thickness. It is most significant, however, that the normal spaces for the $2^1/_2$-mil paper are just about one-half the normal spaces for the five-mil paper and that likewise the maximum spaces for the thin paper are also half as large. The wafers show this advantage of the thin paper very clearly. It is recognized that in long sections of cable there is some probability of spaces occurring that will be equal to twice the tape thickness but extremely improbable that spaces appreciably greater than this will occur in modern cable.

It is natural that such a system as described in each of these two papers did not grow full-fledged at one time and that there are some parts which are not entirely new. The authors have been concerned primarily with giving engineering information concerning a successful system which it has been their job to improve, rather than with writing a bibliography, but they are pleased to have Mr. Wyatt express his opinion as to where certain credit should be given.

We are very pleased that Mr. Thomas has mentioned his sheath-compensated cable as it has many things in common with the compression type of cable. In this connection, it is interesting to note that some of this cable which we manufactured in 1935 is still operating with a record of no inherent faults to date. In this design vulcanized rubber tapes are applied over the lead sheath at a tension of 1,000 pounds per square inch. The elasticity of these tapes causes the lead sheath to compensate for the internal expansion and contraction caused by load changes and thus prevents void formation.

In reply to Mr. Thomas' questions, laboratory tests show that fatigue strength of the lead cable sheath when subjected to vibration or bending is considerably increased by the elimination of oxygen from contact with the sheath surface. In reference to the countersunk connector, this is of the soldered type with two short slots on the top for receiving solder. The outside diameter is the same as that of the cable conductor. In order to apply the connector, the outer layer of conductor strands on each of the cable ends is cut back for a distance of half the connector length. When the connector is wiped in place, these strands are flush with the connector and joined to it. In Figure 5 of the paper on compression cable, the step on which the joint sleeve ends is the lead sheath of the cable. The next step is the termination of the sheath-reinforcing tapes. No void space is left under the joint sleeve. Varnished cambric tape is used to build up the diameter of the sloping ends over the shielding braid to a dimension equal to the inside diameter of the lead sleeve. This diameter is carefully checked in order to secure a tight uniform fit along the full length of the sleeve.

Approximately 60 per cent of the commercial line was installed under paved city streets. About 50 per cent of this line was installed under streets using the heavy paving, 10 per cent under streets using light paving, and the remaining 40 per cent installed where no paving existed. A cost estimate made of the circuit indicated that the total cost to install oil-filled cable in conduit with accessories would be about 20 per cent higher than the cost of a high-pressure gas-filled pipe-type cable installation.

The paragraph questioned by Doctor Whitehead does not make the conclusion that the stress in the gas spaces is less than that in the other types of insulation. This paragraph is intended to point out that to whatever extent presence of gas reduces the over-all dielectric constant, the stresses in the oil and paper are, thereby, correspondingly reduced. Thus at any given applied voltage, the stress in the oil and paper will be (slightly) lower than on other types of cable such as oil-filled, Oilostatic, or compression cable. For all voltages at which there is no ionization in the gas space the electrical stress in the oil and paper will have no effect not found at least equally in these other types; or as stated in the paper, stress below the ionization voltage in the gas should have no effect on the insulation.

It has been pointed out by Doctor Whitehead and others that there is undoubtedly some ionization at voltages below the level necessary for detection by power-factor measurements. It will be interesting to study this by the more sensitive type of measurement such as used by Doctor Whitehead and by Professor Paine. However the shape of the voltage-time curve of Figure 13 shows that no harmful ionization occurs appreciably below the voltage at which we have measured ionization.. Above the critical voltage indicated by the short horizontal section of the curve, the life decreases rapidly with increasing voltage. Below this critical stress, application of voltage has no effect on the life of the cable. An additional point on this curve has now been secured—one cable length has failed after a life of over 1,600 hours at an average voltage of 155 kv. This test was begun at 148 kv, voltage being raised uniformly, ending at 163 kv. While there is some variation from one length to another as shown by some scattering of points on the curve, a constant voltage that does not produce failure in 100 or 200 hours apparently will never produce failure.

It is obvious that, above the critical stress, the extent and destructiveness of the ionization increase rapidly with increasing voltage; the converse is also true, the extent and destructiveness rapidly disappear as the voltage is reduced below the critical value. Since there is, of course, some longitudinal nonuniformity, the critical stress on some specimens will be lower than on others and will be lower than for the average curve that is drawn. From the evidence from severely handled specimens, the minimum critical value appears to be not very far below 140 kv, or twice the working pressure of this cable. Thus, as far as concerns the normal 60-cycle voltage, there is a wide margin permitting future increases of stress by reduction of insulation thickness. This margin is indeed greater than the very considerable margin that exists in the surge strength so that the ultimate reduction in insulation thickness will doubtless be determined by surge strength rather than by 60-cycle strength.

Doctor Wiseman considers the restraining force measurements on the 50-foot sample as inconclusive because of the short length. It is true that the section was short as compared with actual sections, but still it was of sufficient length to permit the cable to take freely the same configuration in absorbing the longitudinal expansion as would occur on a long section, and therefore it is felt that these values are representative of the maximum values of thrust that may be encountered on an actual section. At the most the criticism of the test is merely to the effect that the small easily handled thrust measured may be even less in an actual installation. In calling attention to the coefficient of friction for *SMD*-type cable when pulled into steel pipe, Doctor Wiseman states that 0.37 is very good for dry pipe, but for Oilostatic, where the cable oil also acted as a lubricant, they got a value of 0.26. In the paper it was stated that 0.37 was the maximum value (not average value) that was reached for any section in the seven-mile line including the sections with bends. The average value was considerably below this. Since the coefficient of friction inherently varies over such a wide range, depending on many factors that cannot be evaluated exactly, the average value was not given, since it is felt that without knowing these controlling factors the average value of this coefficient is of doubtful significance. It should be pointed out that petrolatum was used as a lubricant and was applied over the half-round open spiral wires before the lead sheath was applied. Since petrolatum is a better lubricant than cable oil, the *SMD*-type cable can be expected to have a lower coefficient of friction than Oilostatic cable, since otherwise the external structures are similar, and therefore the maximum pulling length would be at least equal to Oilostatic cable.

It is very helpful to have Mr. Main's supplemental information concerning compression cable. His confidence in the value

and reliability of this type of cable is based upon the very practical ground of successful production and operation of a considerable amount of it. In addition to his general comments, he tells of significant modifications of earlier designs. These should be especially helpful wherever the self-contained type is applicable.

Mr. Main grants certain advantages of the pipe-type cable but evidently is more impressed by the merits of the self-contained type. For smaller amounts of power than being carried at Detroit, these merits will often predominate, but where large conductor sizes are required as is generally the case in this country, the pipe-type system proves to be the more practical.

We are glad to have Mr. Main's figures of power factor at 20 degrees centigrade for the British-made cables and note that these are somewhat more than 0.1 per cent lower than the values given in our Figure 7 for the field measurements on the experimental compression cable. Much of this difference is accountable by the fact that density of the paper in the Detroit cable is very high, with a corresponding reduction in the amount of oil. With very low loss oil, such as used in this cable, the power factor of the paper substance is higher than that of the oil. Thus the greater paper content means greater over-all power factor. Any difference that cannot be accounted for in this way is only a fraction of a tenth of one per cent and can be explained by the difference between measurements made in the field as compared with the more accurate factory measurements. Thus Mr. Main checks our values which were questioned by Mr. Wyatt.

There is not space here to discuss fully the practical importance of the high-density paper. It suffices to point out that the large reduction in oil content results in proportionately less volume change with temperature than with lower-density paper. Incidentally, there is also a gain of this sort from the compact strand as compared with conventional. The much wider temperature range thus required for a given volume change is vastly more important than any minor difference in loss due to the difference in power factor.

In referring to the causes "contributory to the satisfactory solution of gas-filled cable," Mr. Main suggests that several of these have been developed by various cable manufacturers for the improvement of super-voltage cables generally. That is fully conceded. Some of these are of course particularly significant for the gas-pressure cable.

Mr. Main suggests that the reduction in stress in the impregnated paper by reason of the lower permittivity of the gas may reduce the emphasis that need be placed upon the quality of the saturant in the gas-pressure cable. We have drawn attention to this reduction of stress but would emphasize that it is purely incidental and actually amounts to only a few per cent. He asks if the viscosity of 3,000 given for this saturant is correct and not wrong by a decimal point. Three thousand voltage is correct, and we are glad to have the emphasis placed upon it that comes from the question. We believe that the properties of the saturant used, including this high viscosity, are very significant.

We quite agree with Mr. Main concerning relative impulse strength of different types of cable. We would be surprised if oil-filled cable made with the same type of paper and with strand shielding would not have as high impulse strength as this cable, although it is to be noted that preimpregnation facilitated the use of very thin tapes without the mechanical difficulties which Mr. Shanklin has found in applying unimpregnated thin tapes.

Mr. Main brings together for comparison our statement that the minimum safe-operating pressure is 100 pounds per square inch and our statement that the cable may be given standard acceptance voltage tests at 30 pounds per square inch. The operating limitation is, of course, conservative. There is, however, no particular advantage in setting a lower limit, since the line and accessories will readily take care of 200 pounds per square inch or more, and the cable will be operated at that pressure. As far as concerns test practice in this country, acceptance tests are made at voltages far above what anyone would consider to be a safe-operating voltage. It is true that this is exaggerated by the suggestion of making a normal test at a pressure lower than suggested for operation. However, it is to be noted that the dielectric strength for a period of a few hours is reduced not more than 10 per cent or 20 per cent at 30 pounds per square inch as compared with 225 pounds per square inch. It is this fact, as well as the results of dissection of tested samples, that warrants the testing for 15 minute periods to be made within the same range as is customary for oil-filled cable.

Mr. Main comments concerning the radial power-factor curves, saying these give no indication of the effect of the gas space on the shape of the curve. We see no reason for this concern; the curve actually obtained explores fully the variations of the impregnated tapes, and this seems to us to complete its purpose. Mr. Main himself recognizes this function when he "wonders what would be the shape of the curve" without humidity control in the factory. Actually these tests show how effectively that control was accomplished, and similar tests were a helpful means in setting up required standards for that control.

Mr. Main brings question as to the meaning of the same paragraph which Doctor Whitehead questioned. Our answer to Doctor Whitehead substantially answers also Mr. Main. The statement we wish to emphasize is a corollary of one Mr. Main makes that "the electrical strength of the paper cannot be used to full advantage; otherwise the gas spaces would be overstressed and destructive ionization result." But this means that if we avoid destructive ionization in the gas spaces we need feel no concern about the electric stress in the oil and paper. This fact is so very obvious that there was a tendency to look for some different and less easily accepted meaning. But this leads directly to the conclusion that the electric stress in the oil and paper in this cable is well below that which long experience with other types of cable has shown to be without harmful effect.

Mr. Main refers more than once to "difficulties" of stripping the sheath; he feels that this involves "costly complications." Before making the experimental installation, this seemed somewhat of a problem, but, by the time of the commercial installation, no problem remained. We can assure Mr. Main that his fear on that score is without foundation. Indeed we are constrained to remark that Mr. Main's comments emphasize our previous remark that both of these systems are good and very practical. Those acquainted with one will be partisan to that while fearing unfamiliar problems of the other. Acquaintance with both emphasizes the value of both.

Mr. Peterson has asked the expected life of the pipe when protected by one half inch Somastic as was applied on the Detroit commercial line. We have not been able to find any case of corrosion or deterioration with this type of protection, and installations have now been in service up to ten years. In regard to expansion, the expansion bend was provided only in the experimental installation and was used only to take care of expansion in the armored compression cable. No expansion provision is necessary for the pipe itself. In the *SMD*-type cable the three conductors have considerable freedom for movement and can absorb the longitudinal thermal expansion without any other special provision. As to the viscosity of the impregnating compound used on the *SMD* cable, it is about 80,000 at 50 degrees centigrade in terms of Saybolt Universal seconds.

No effort was made to determine the moisture content of the soils encountered because of the poor correlation that appears to exist between moisture content and thermal resistivity in an actual installation. This may be attributed in part to the difficulty in securing a moisture-content sample that is representative, as well as to the fact that for the Detroit installation the ground water level has a greater effect on the thermal resistance of the soil. A record was maintained of the rainfall, and it was found that this as such had practically no correlation with the seasonal soil resistivities reported.

Mr. Del Mar has concisely summarized the limited available knowledge on the subject of earth resistivity, and it was because of this inexact knowledge that these earth resistivity measurements were made and presented at this time. Several discussers have asked for more information concerning the thermal-resistivity measurements or concerning the thermal characteristics of the high-pressure pipe-type cable systems, or have asked why more data were not presented on this subject since more were obtained. These tests have not been completed.

The discussions by Meyerhoff, Johansson, Frank, and D'Eustachio, all of whom are associated with two of the authors may be considered as supplementary to the authors' closure.

The Dielectric Strength and Life of Impregnated-Paper Insulation—III

Discussion and author's closure of paper 42-92 by J. B. Whitehead, presented at the AIEE summer convention, Chicago, Ill., June 22–26, 1942, and published in AIEE TRANSACTIONS, 1942, August section, pages 618–22.

G. B. Shanklin (General Electric Company Schenectady, N. Y.): There has been a good deal of speculation about Doctor Whitehead's breakdown results being at variance with actual solid-type cable experience, as regards paper density. The following explanation is offered for what it is worth.

Because of entire absence of void formation, Doctor Whitehead's test samples are actually representative of oil-filled cable and not solid-type. The mechanism of breakdown he is studying is, accordingly, applicable in all detail only to oil-filled cable. This is borne out by the fact that his results are in full accord with oil-filled-cable experience.

For times expressed in seconds or fractions of a second (impulse, and so forth), the dielectric strength of oil-filled cable increases with increase of paper density. For times in hours, such as Doctor Whitehead used, the dielectric strength decreases slightly with increase in paper density, just as he found. For times expressed in months or years, change in paper density, over the usual commercial range, has practically no effect on dielectric strength.

Ionization in voids of solid-type insulation can easily change these trends, particularly for the longer periods of time. The action is more complicated and more difficult to reproduce in the laboratory, because it depends on size, quantity, and location of these voids, as well as pressure and numerous other factors. For this reason I suppose we will always have differences of opinion about the effects of paper density in solid-type cable, or in any other type of cable where incipient failure is brought about by gaseous ionization in voids. Personally, I cannot get very excited about it, because the differences are not great in any case.

If Doctor Whitehead needs any support in his belief that Robinson was wrong in concluding that *all* failures are instigated at the conductor surface, I stand ready to give it. Like Doctor Whitehead, I have examined plenty of incipient failures at locations other than the conductor surface, and this was in full-sized cable, some of which had relatively large ratios of maximum to minimum stress.

Too many factors besides quantitative stress are involved for one to say that the location of breakdown in paper-insulated cable follows a simple physical law, based on the geometrical stress field alone.

In overstressed gas-filled cable, for instance, ionization deterioration is usually more pronounced in the outer zone of the insulation thickness rather than the inner zone, and final failure usually starts here. This occurs, because compound drainage is considerably more in this outer zone, and voids are larger.

There are many champions of the maximum-stress theory and some champions of the minimum-stress theory. The fact remains, however, that practical design work in the whole cable industry is based on neither but, instead, is based on average stress. My experience has been that over the usual commercial range of conductor sizes, insulation wall thicknesses, and so forth, average stress expresses practical results better than anything else. This middle of the road course is a safe one to follow in all but extreme and special cases.

William A. Del Mar (Phelps Dodge Copper Products Corporation, Yonkers, N. Y.): Doctor Whitehead's modification of the Robinson coring theory is very interesting.

Like Robinson he finds that initial trouble arises in an oil space and that the oil space involved is one where the greatest electrical stress occurs.

However, because of the circumstance that his insulation is thin compared to his conductor diameter and that his conductor is smooth, he regards it as a matter of chance whether the stress is greatest at the inner surface of the insulation or at some intermediate layer.

Perhaps there is another reason. Reference to P. L. Hoover's 1926 paper shows that the maximum stress at very high stress is not at the conductor surface but within the insulation, and this may influence the results obtained.

Again, Doctor Whitehead agrees with Robinson that failure originates in gas in the oil space, but, whereas Robinson postulates a gas occlusion, Whitehead says that if there is no gas occlusion present, and the stress is sufficiently high, the stress will generate the gas by ionizing the oil.

This immediately suggests two levels of dielectric strength, one applying to practical cables from which complete gas exclusion is impossible, and a higher level applying to completely gas-free laboratory specimens like those of Doctor Whitehead.

I shall try to establish the fact that Doctor Whitehead's specimens fail at a higher stress level than cables and will then try to draw the consequences.

Reading over Doctor Whitehead's three papers on stability of oil-impregnated-paper insulation, I find that all stresses referred to are average stresses and that, where the expression "maximum stress" is used, it means "the maximum or final value of the average stress."

Thus, Figure 1 of the paper gives an average final stress of nearly 600 volts per mil for a specimen made with paper of specific gravity of 0.896 and designated as *B* paper, after being subjected to 13 stages at average stresses starting at 400 volts per mil.

The same Figure 1 gives, for this paper, a life of 53 hours, practically all of which was consumed in the 13 preliminary stages.

We have no exact way to correlate the preliminary steps with the final steps, but we may make an approximation by assuming that each stage causes deterioration at a rate proportional to the 20th power of the stress. If you ask the source of this figure, I can give you nothing better than some test data on oil-filled cables which suggested it. In the case of single-conductor solid-type cable, the index is about 6.

On this basis the preliminary stages are equivalent in the aggregate to about $4^1/_2$ hours at the final stage for all the papers tested.

Returning to the *B* paper, if we plot the original test data with volts per mil as abscissas and hours as ordinates, we obtain a gunshot diagram with average stresses ranging from 581 to 700 volts per mil and lines ranging from 0.2 to 3.83 hours.

If we average these lines, we obtain about 2.3 hours, but this would not be a significant average, as it would not take into account the various stresses at which the individual lives were obtained. This may be allowed for in an approximate way, by the same assumption made above, that is, by assuming the life to be inversely as the 20th power of the voltage and obtaining a weighted average based on that assumption. This gives a life of $3^1/_2$ hours.

If we add this to the $4^1/_2$ hours from the preliminary stages, we obtain, for paper *B* specimens, an empirical life of eight hours at 600 volts per mil.

The nearest comparable cable test data are those from the Association of Edison

Table I

Paper Density (Gurley) Seconds	Specific Gravity	(Volts Per Mil) Overlap $33^1/_3\%$	$37^1/_2\%$
33	0.74	349	342
480	0.78	420	367
3,000	0.94	390	428

Illuminating Companies "Time Test," which give failures for single-conductor cables with thin walls at average stresses of about 400 volts per mil after

6 hours at 220 volts per mil
3 hours at 300 volts per mil
3 hours at 350 volts per mil

In the case of solid-type single-conductor cable, an index of 6, instead of 20, gives a more accurate means of weighting the lines. On this basis, the preliminary stages give the equivalent of about two hours at 400 volts per mil. The tests usually run from one quarter to three quarters of an hour at 400 volts per mil, a fair average being not over one-half hour. This added to the two hours from preliminary stages, give $2^1/_2$ hours at 400 volts per mil.

By this roundabout route we arrive at the following comparison between Doctor Whitehead's specimens and ordinary cables.

	Failure Stress (Average) Volts Per Mil	Time at Failure Stress (Hours)
Doctor Whitehead's specimens	600	8
Cables	400	$2^1/_2$

This seems to establish that Doctor Whitehead's specimens fail at a definitely higher stress level than solid cables, this level being at least 50 per cent greater. If the comparison is made on the basis of final stresses only, Doctor Whitehead's specimens appear to have at least 75 per cent greater dielectric strength.

In the case of failure by generated gas, the stress on the oil is all important, as the generation of gas is directly dependent thereon and becomes violent when this stress is exceeded. Therefore, in the laboratory specimens, the specific inductive capacity of the paper is of prime importance, and a high value works against high dielectric strength, as pointed out by Doctor Whitehead.

Where, however, failure is due to occluded gas, ionization starts at a low stress, whatever the density of the paper, and the stress at failure depends on the ability of the paper structure to prevent spread of the ionization streamers, an ability which increases with increasing density, provided that the tangential path is not weaker than the path through the paper. We have made extensive tests on specimens made purposely with poor impregnation which completely support this view. A progress report on this was presented to the National Research Council's Williamsburg conference in 1941 and referred to by Doctor Whitehead in his paper. Details of this investigation will be offered to the Institute when the exigencies of more important war work permit.

In the meanwhile typical data on poorly impregnated specimens ten tapes thick are offered in Table I for comparison with Doctor Whitehead's.

The voltage was increased by five-minute steps, each step being 20 per cent higher than the preceding one. These were converted to an arbitrary equivalent one hour dielectric strength by means of the sixth root law.

The above figures are the average of eight breakdowns. The maximum deviation from the average was 8.9 per cent, and the average deviation 4.5 per cent.

It will be noted that at $37^1/_2$ per cent overlap, dielectric strength increases with density whereas at $33^1/_3$ per cent overlap, the relative dielectric strengths of the papers and tangential paths produce a condition wherein a maximum occurs at a medium density.

R. W. Atkinson (General Cable Corporation, Bayonne, N. J.): Doctor Whitehead's studies are leading to a better understanding of the phenomena occurring in dielectrics under high electric stress. The very fact that certain of the conclusions from his tests were originally so unexpected by "dielectricians" greatly emphasizes the importance of these results in our understanding of the effect of electric stresses.

Why some of the relationships differ from those found in commercial cable insulation is not yet obvious, although the explanation may be found among the theories that have been suggested by various people. Since these things are susceptible of effective experimental attack, the explanation will be forthcoming when sufficient effort can be devoted to the subject.

J. B. Whitehead: When our first results on the influence of paper density on dielectric strength were announced, there was considerable disquietude amongst cable engineers who were following closely the progress of our work, and some of whom advocated the use of high-density paper. There was some evidence that the accuracy of the results was questioned. As they were substantiated by further data, cable engineers united in an effort to collect from their own laboratories results of tests in favor of high-density paper. Reports were received from five or six laboratories, but, with one exception, all the tests had been made on continuous sheets of paper and indicated increasing dielectric strength with increasing paper density, in accordance with theory and long-established behavior of other materials. The single exception noted was one impulse-voltage test on each of two cables, one with high density and the other with low density paper—the higher density giving a somewhat higher breakdown strength.

Much of the uncertainty of the situation thus created was due to the impossibility of reconciling our results with the behavior in breakdown tests on solid-type cables; this, in spite of the fact that we have emphasized the absence of free gas in our samples, and that our results, if applied to cable behavior, should be confined to those of oil-filled type.

We have never ventured to suggest the extent to which our results should be considered in cable design, leaving this question to the vastly wider experience of cable engineers. However, in the face of some questions and criticism, we have ventured from time to time to ask for the experimental evidence on cables, which was at variance with our own. None worthy of the name has been forthcoming. Mr. Shanklin goes further than others in stating the results of manufacturers' experience. It would be helpful if he would give some quantitative data substantiating his statements as to the relative influence of paper density in impulse, short-time, and long-time testing, respectively. Requests for quantitative data from those manufacturers who advocate the use of high-density paper have always been met with the response that their experience was of general character over a period of years and that it would be difficult to separate the particular studies which had led to conviction that a denser paper results in higher dielectric strength. Hardly a convincing reply, in view of the number of factors which have entered into the general improvement of cable quality within recent years.

As stated above, it is not our intention to question the experience and practice of cable manufacturers, nor even to suggest the extent to which weight should be given to our results. I believe, however, that there is now no question of the accuracy of our results on the influence of paper density in our type of sample. This means that the influence of the relative values of the dielectric constants of cable tape, and of oil channel or gas space, is such as to throw an increased value of stress into the oil channels and gas spaces, and that this stress increases approximately as the density of the paper. Whether or not this fact shows itself only at relatively high stresses, as in our experiments, as pointed out by Mr. Del Mar, the fact remains that, if failures do originate in oil channels and gas spaces, the use of higher-density paper increases the stresses in these most vulnerable locations. It does not appear to me that the question has been satisfactorily answered, and it is to be hoped that somehow, somewhere, after the present unhappy period, further experiment may be possible for clearing it up.

Load Ratings of Cable—II

Discussion and author's closure of paper 42-111 by Herman Halperin, presented at the AIEE summer convention, Chicago, Ill., June 22–26, 1942, and published in AIEE TRANSACTIONS, 1942, pages 930–42.

G. B. Shanklin (General Electric Company, Schenectady, N. Y.): Mr. Halperin has made another valuable contribution to cable engineering. Systematic operating data of the kind he presents can only be obtained directly in the field by a large, well-organized operating company. This is particularly true of the behavior of cable under heavy load conditions, and it is about this that I wish to comment.

For a number of years some engineers have been advocating rather extreme loads and copper temperatures for power cable, limits that appeared to many of us to be contrary to actual experience. It is interesting to note that, based on the extensive field study he has been making the past two or three years, Mr. Halperin has reached relatively moderate views about normal safe loading. This is summarized in Table VII of his paper, representing the latest maximum copper temperature practice in Chicago. For normal operation of solid-type cable he follows the well-known standard rule of $(90 - E)$ degrees centigrade in all but three instances. At the minimum and maximum voltage ratings he increases copper temperature by five degrees centigrade, while at one intermediate voltage rating he decreases temperature by five degrees centigrade, as compared with the standard rule.

My only disagreement is with the recommended limit of 65 degrees centigrade for 66-kv solid-type cable with solid filled joints. I do not believe there is enough actual field experience to verify this and feel that even the present standard rule limits for 33-kv three-conductor and 66-kv single-conductor cable are too high.

For wartime loading conditions Mr. Halperin is recommending from three degrees centigrade to ten degrees centigrade increase over normal conditions, but emphasizes that increased service failures and shortened life of cable resulting therefrom must be expected and accepted. This, to my mind, is the core of this whole problem of heavy cable loading. It is not a question of obtaining something for nothing but of weighing the gains against the losses.

Mr. Halperin is recommending occasional short-time emergency overloading of five degrees centigrade to 27 degrees centigrade above normal loading and seven degrees centigrade to 35 degrees centigrade above wartime loading. Only in the recent past have we begun to think in terms of a 15 degrees centigrade tolerance for emergency overloading. I suggest that we obtain some experience with this limit before going too far. Mr. Halperin points out that he does not know what might happen to accessories under such extreme temperature ranges, and it is again a question of weighing the gains against the losses.

Mr. Halperin states that in some cases considerable thermal advantage may be gained by making relatively deep installa-

tions of underground ducts. This is undoubtedly true and is particularly true of the Chicago district, but it depends upon the permanent underground water level. If this can be reached, there is a material cooling effect on the loaded cables. If not reached, there is practically no difference in cable heating at any depth from $2^1/_2$ to 12 feet, the cooler earth at greater depth being counterbalanced by the higher thermal resistance to earth's surface and other factors. It is for this reason that standard load ratings of cable would be greatly simplified if we standardized on a depth of three feet and earth ambient temperature at that depth, ignoring the actual depth at which the cable is laid. The chances are, in any case, that the depth will vary from one end of a line to the other.

J. B. Whitehead (The Johns Hopkins University, Baltimore, Md.): In reference to Mr. Halperin's paper and to the evidence of discharges from an oil layer between the insulation and the surface of the sheath, contact with both lead and paper of this oil layer of appreciable thickness would certainly result in an increased ionic content of the oil. This would lead to space charge layers at the surfaces of both sheath and insulation with resulting high local stresses leading to local bridges, or local failures, or abnormally high stresses because of surface irregularities.

To refer to Mr. Halperin's paper and to the question of the mechanism of failure, the following may be said: A thorough failure with even a moderate amount of burning is usually sufficient to completely conceal the first cause of failure. Failures in this type of insulation almost invariably originate in an oil channel in which the spark is due to high local stress at the interface between paper and oil. A gas bubble is formed by the initial spark, and cumulative ionization then begins. The consequent burning or boring through the insulation wall is not reflected in a change in the over-all power factor of the sample, until the failure is almost complete and is such that a heavy increase in the conduction component of the current may result. These statements are largely based on accounts of many partial failures reported in my paper on today's program.[1]

Will Mr. Halperin please explain the statement that cable samples made with very thin insulation will show more definite deterioration than thicker samples?

1. The Dielectric Strength and Life of Impregnated-Paper Insulation, J. B. Whitehead. AIEE Transactions, volume 61, 1942, August section, pages 618–22.

L. F. Hickernell (Anaconda Wire and Cable Company, Hastings-on-Hudson, N. Y.): This paper is so complete that it leaves few, if any, important questions to ask the author. In referring to the section titled "Oil-Filled Cables," it is noted that cable *T*-0.500 developed an increase in power factor due to the excessive sheath expansion drawing in core oil of high power factor. The cause of the high power factor of the core oil is not stated. If it is assumed that the oil was not abnormal, the operation could be considerably improved by carbon-black protection over the conductor. This would not only reduce the maximum stress, but would also improve the power factor of the core oil by adsorption. Similarly, if carbon-black tapes were used over the insulation, the severe discharges between the sheath and insulation would be eliminated, and the additional volume of carbon black would be helpful in conditioning the oil.

In conclusion 2 of this section, in the "Note," it is suggested that these investigations may be applicable to other oil-impregnated insulation, especially transformers. No doubt the transformer designers will discuss this point. However, in the event a cable session may escape their attention, I should like to point out that, to the best of my knowledge, the paper insulation used in transformers is quite different from the wood-pulp paper developed for cables, and hence the results obtained on the latter do not apply to the former.

In "Aging Tests of Three-Conductor Solid-Type Cable," the following statement is noted: "The special shielding tapes were either metallized-paper tapes or carbon-black tapes." Shielding, or stress control, is only one of several functions exclusively obtained in the carbon-black construction as ably demonstrated by Rosch[1] and further substantiated in subsequent investigations which will be published shortly.

In reference to "Mitigation of Sheath-Crack Troubles," it may be of interest to know that a terminal employing a flexible copper hose has been in successful service where formerly trouble had been experienced with lead sheaths due to fatigue from vibration. Similar construction could be employed in manholes though subject to some of the difficulties of the Sylphons pointed out by the author.

1. The Type *CB* Impregnated-Paper Cable, S. J. Rosch. AIEE Transactions, volume 59, 1940, pages 1041–9.

J. G. Stelzer (The Commonwealth and Southern Corporation, Jackson, Mich.): Mr. Halperin mentions that the movement of cable in ducts clogged with fine silt was much less than in ducts free of silt, this lesser movement being attributed to the increased friction caused by the silt. Isn't it possible to attribute, at least in part, this difference in movement to the fact that the heat radiation was much better in the ducts that were clogged with silt, thus reducing the over-all cable temperature with a corresponding reduction in expansion? It seems that this would be particularly true if the silt was moist.

Is joining any particular problem when cables are worked to the emergency war temperatures as given in Table VII? Are there any particular problems to be expected in connection with the migrations of the solid compounds?

In connection with the mitigation of sheath-crack troubles, we have had numerous installations where the cable movement at duct mouths was strictly limited by heavy concrete fireproofing. These cables all have a long record of continual operation with no reports of cracked sheaths or sheath abrasion troubles.

In localities where there are lead sheath corrosion troubles, will the increased temperatures under the emergency war loadings have any effect on the rate of corrosion? If so, in what way?

Table VII shows the maximum allowable conductor temperatures for normal and emergency operation. Conductor temperatures do not ordinarily mean much to operating men, and it is necessary to convert such ratings into terms of amperes for given periods of time. This conversion from temperature to amperes is a subject on which there does not seem to be much information available that does not involve calculations having factors that are not ordinarily available without considerable investigation. What method is used for converting these temperature ratings to amperes for the use of the operating personnel?

No mention is made of sheath swelling and bursting due to migration of impregnating oils. This is probably not much of a factor in the Chicago area where the contours are in general comparatively flat. Troubles of this nature probably are to be expected in hilly sections of the country if the emergency war loadings in Table VII are permitted.

Robert J. Wiseman (The Okonite-Callender Cable Company, Inc., Passaic, N. J.): Mr. Halperin's paper will be an aid to all who operate power cables in pointing out some of the important factors in installation and operation. I was very much impressed with the second paragraph under "Introduction." It summarizes very clearly the difficulty we have in trying to set up rules of procedure regarding power cables, and why it appears at times that the manufacturer will not give a clear-cut statement as to what a cable will do under certain conditions. I think everyone should read this paragraph and memorize it.

When comparing the results Mr. Halperin gets for the change in tearing strength of the paper after aging as a measure of deterioration with the results obtained at Massachusetts Institute of Technology in 1926–29, we should understand that the technique of cable manufacture has improved so that modern cables have less air and moisture, and better paper and oil, so that a longer life insulation should result.

Mr. Halperin refers to the breakdown of the outer tapes next to the sheath. As this is oil-filled cable, it seems as if the normal working stress would not cause failure, even though the oil had shown signs of deterioration, but the lightning and switching surges could start failure.

The views expressed regarding improvement in the thermal conditions surrounding a conduit system by replacing soil of high thermal resistance by soil with low thermal resistance or burying the conduit deeper are also applicable to buried cable systems. As Mr. Halperin states, going to greater depths results in a more constant ambient temperature independent of air temperature and a higher moisture content in the soil which is very helpful in lowering the thermal resistance and improving the heat dissipating properties of the duct or cable.

The emergency load temperatures proposed by Mr. Halperin seem reasonable for his company in view of his experience. As we can expect the loads on present-day cables to be raised because of war condi-

tions, we can also expect the cable failure rate to increase. This will have to be accepted, but, fortunately, as Mr. Halperin brings out in his paper, some factors add and others subtract in their effect on operation, and so the net result seems to be that the cables will operate, even though we expect them to fail.

R. W. Atkinson (General Cable Corporation, Bayonne, N. J.): The subject of overload ratings of cables is being placed on a scientific basis by such contributions as Mr. Halperin's. In the absence of numerical data, the manufacturer was inclined to point out the dangers of any increase of rating above normal, sometimes indicating some of the directions from which such danger might come. On the other hand, the user who wished to be able to obtain an increased rating was inclined to discount the general warnings and to wish to base ratings only on proved limitations. The result was a wide difference in recommendations and no engineering basis by which these could be reconciled.

A further important difference has had to do with acceptance that exigencies or even economics of operation may justify deliberate shortening of cable life. The manufacturer was opposed to accepting a rating that might shorten life; the user was inclined not to recognize that increased ratings might affect the life unfavorably. The war emergency has made easier the resolution of this difficulty.

With this better viewpoint and with the data and analysis presented by Mr. Halperin, we have now reached a common ground where these ratings may be considered objectively and determined on a scientific basis with little difference of opinion between manufacturer and user.

William A. Del Mar (Phelps Dodge Copper Products Company, Yonkers, N. Y.): Mr. Halperin's paper stands out as a valuable contribution to the war effort, inasmuch as it points clearly and specifically to means of conserving copper and enabling the utilities to carry on, for the duration of the war, with existing equipment. He also suggests new and higher temperatures for normal operation.

The conclusions were reached as the result of studies on one of the largest cable systems in the country, where no effort has been spared to obtain the best possible operating conditions, even to the extent of enlarging a great number of existing manholes, and eliminating thermal bottlenecks.

Many cable systems do not enjoy these advantages, largely because of less favorable economic conditions; high temperature operation may, therefore, prove less successful. This is particularly the case where manholes are restricted in size, load factors are low, cables are old and deteriorated, and maintenance less than ideal.

It is, therefore, to be hoped that Mr. Halperin's proposals for normal operation will be accepted by other utility engineers as a challenge to bring out data either in substantiation or rebuttal.

Herman Halperin: As Mr. Shanklin correctly points out, in establishing increased load ratings, the gains due to greater utilization of cable circuits must be carefully weighed against the losses caused by reduction in life and by an increased rate of failures. In the present national emergency the problem is to obtain the maximum possible utilization in order to preserve critical materials without having these losses become very serious. As indicated in my discussion of the group of papers by Sporn, Gaty, Cole, and others at the AIEE winter convention in January 1942 (AIEE TRANSACTIONS, volume 61, page 432), it seems, however, shortsighted to increase loadings of cable, transformers, and so forth, so much that numerous troubles requiring extensive replacements of equipment will occur in a few years or, perhaps, before the end of the war. The emergency ratings are based upon the consideration that the cable would be subjected very rarely to such conditions and that the reduction in life caused by such occasional operation would, therefore, be comparatively small, while the advantage of the consequent general higher level of loading would be large.

Mr. Atkinson and others give emphasis to the advantage of obtaining and studying considerable field and test data in arriving at allowable temperatures and loading. As a result, the differences in opinions are decreasing. This sort of observation gives emphasis to the continuing need for convention sessions and discussions such as today's. These advantages become further obvious when it is realized that available information shows that European temperature limits for cable in 1939 were 0 to 20 or 25 degrees centigrade less than prescribed in regular American specifications and standards, and were still further below the limits given for emergency operation in my 1939 paper "Load Ratings of Cable."[1]

With regard to Mr. Shanklin's discussion of the advantage of deeper installation of conduit and cable, this method is used as an alternative to replacing poor soil, only if at the lower level better soil conditions prevail. Our test data on temperatures in and around conduits indicate definitely that the heat does not all come to the surface, but is conducted in all directions to the surrounding earth in accordance with the temperature distribution and thermal resistances. The thermal sink is not necessarily at the surface of the ground, especially in the summer. Also, with the lower conduits, the maximum base earth temperatures become four or six or eight degrees less in the summer, and this is usually of advantage because summer load ratings are becoming more and more the limiting ratings on cable. His suggestion to standardize on a definite depth for thermal rating is followed by the Commonwealth Edison Company in that all standard ratings are based on an assumed distance of four feet between the center of the conduit and the surface of the ground.

Concerning Mr. Shanklin's point on my proposed temperatures for normal daily loading usually being not greatly different from those in regular American specifications, it should be noted that the temperatures in those specifications were almost always used for special conditions. In other words, the usual daily temperatures were actually much below the temperatures given in the specifications. With the new temperatures given in my paper for emergency loading, a utility can, as a practical matter, load cables to have in normal daily operation temperatures such as in the specifications, or somewhat higher for wartime, as I indicated.

As to Mr. Shanklin's criticism of my 65-degree limit for solid-type 66-kv cable, I refer to the Halperin–Shanklin paper, "Studies of Stability of Cable Insulation,"[2] wherein it is shown that in laboratory tests at 2.5 times operating voltage, cables were stable with heating cycles to 65 degrees. These cycles were with a room ambient of 20 or 30 degrees centigrade, whereas in conduits the ambients would almost always be higher. Other Chicago tests showed stable cables with heating cycles to 70 degrees.

In connection with the point on the possible ill effects of high temperatures on accessories, it should be noted that these possibilities apply principally to extra-high-voltage accessories and that the accessories usually operate at temperatures substantially less than those for cable in conduit. The ill effects in Chicago were found in a laboratory where the ambient was the same for the accessories and cable.

Regarding Mr. Stelzer's point, I think that silt, provided it is wet, has some effect in reducing the copper temperatures, but the effect is almost certainly inadequate to account for the reduction found in cable expansion. Migration of asphaltic joint compound into cable insulation can cause high power factors adjacent to the joint, but we never experienced any trouble from this cause, because such compounds are used in joints operated at 12 kv and less, where high power factors are of minor importance, and in joints on old 22-kv lines consisting of belted cable having heavy insulation.

The method of converting allowable temperatures into allowable currents cannot be given here because of lack of space but has been described in a paper on "Operating Temperatures of Underground Cables" by C. A. Bauer (1930–31 report of engineering section, Great Lakes division, National Electric Light Association).

In answer to another of Mr. Stelzer's questions, increased temperatures will increase the rate of lead sheath corrosion where such action is already present to an appreciable extent. As to sheath swelling and bursting in hilly country, it is to be expected that impregnating compounds in solid-type cable will flow at usual operating temperatures, and the effect of higher temperatures is to increase the rate of flow. In Chicago we have many risers where the vertical elevation of cable is 20 or 30 feet.

Mr. Hickernell's point on conductor shielding for oil-filled cable seems to me to be particularly applicable for those three-conductor cables with sector conductors having maximum stresses over 200 volts per mil and for hollow-core single-conductor cable. I agree with him that conductor shielding has other benefits besides stress control. As to his point on the difference in papers used in cable and in transformers, some transformer manufacturers advertise their use of "kraft" and "cable" papers and I do not see any substantial reason to expect any large differences between performance of these various cellulose materials and of power cable paper subjected to heat.

In reply to Doctor Whitehead's question, the cables with thinner insulation showed

more deterioration because all samples regardless of insulation thickness were tested at 24 kv, three-phase, with consequently higher stresses on the thinner insulation.

I agree with Doctor Wiseman that the insulation in modern cables should be expected to deteriorate less under heat than it did in the tests of 15 and 18 years ago at Massachusetts Institute of Technology.

Operating experience and studies thoroughly substantiate Mr. Del Mar's points that reasonable manhole sizes and cable training and good maintenance pay excellent returns in the way of longer life of underground circuits and good reliability of service.

The interest shown by all discussions is greatly appreciated.

Frequency Control of Load Swings

Discussion and authors' closure of paper 42-113 by J. E. McCormack and R. J. Lombard, presented at the AIEE summer convention, Chicago, Ill., June 22–26, 1942, and published in AIEE TRANSACTIONS, 1942, September section, pages 623–4.

J. E. Hancock and **H. L. Clark** (General Electric Company, Schenectady, N. Y.): This system of load control really gives to the manually controlled generators a portion of the duty of the frequency-controlling unit since the manual load changes are to be made partially dependent on system frequency. It would appear that in addition to improving load swings on the tie feeders this load-dispatching method should also improve the system frequency regulation.

The two methods described for obtaining the necessary accurate frequency indications show considerable advantage over the conventional frequency meters. The usual frequency meter has also proved inadequate in investigations of steam turbine governor performance. To facilitate these investigations the General Electric Company engineers have recently developed a frequency meter operating on a entirely new principle. This new frequency meter is applicable in the load control method described by Mr. McCormack and Mr. Lombard.

The frequency meter is contained in a metal case approximately 5 by 7 by 10 inches and indicates the frequency of the 110- to 120-volt 60-cycle power system to which it is connected. The total power consumed is approximately five watts. Figure 1 and Figure 2 show the frequency meter which has two scales, one marked from 59.875 to 60.125 cycles per second, and the other from 59.75 to 60.25 cycles per second. Selection between the two scales is made by means of a toggle switch on the instrument panel.

This frequency meter uses a mechanical resonant system consisting of a small 60-cycle tuning fork instead of the usual reactors and capacitors. Since it is well known that the resonance of a mechanical system is, in general, sharper than that of an electrical system, it is readily seen that a frequency meter utilizing this principle may be made extremely sensitive. In fact the range indicated is the broadest that is feasible while a scale of plus and minus 0.01 cycle per second can readily be obtained.

Any mechanical system combining mass and a spring has at least one natural resonant frequency. If a disturbing force is applied to this sytem, the resulting vibration will depend on the relation between the applied frequency and the resonant frequency of the mechanical system. The relative phase angle between the disturbing force and the resulting vibration will shift through nearly 180 degrees in the narrow frequency band corresponding to the resonant peak.

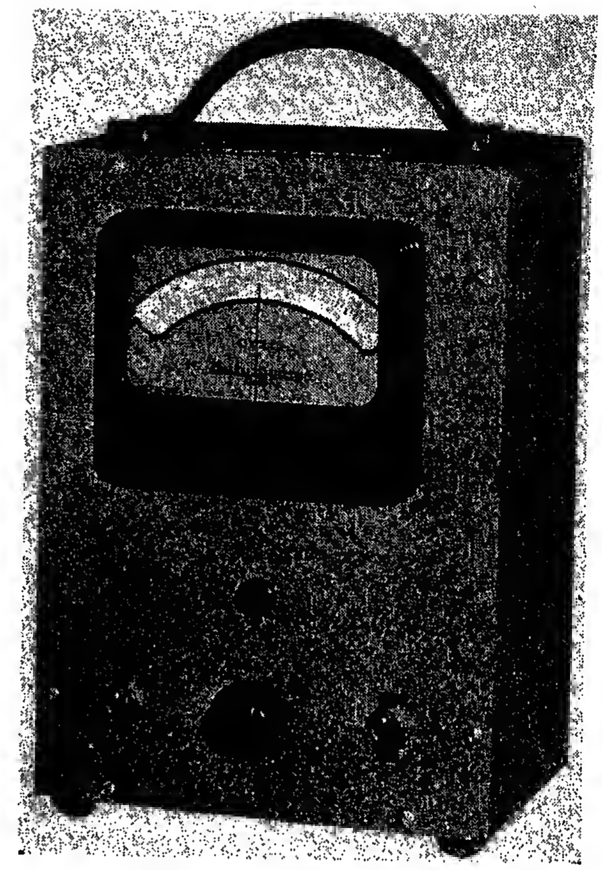

Figure 2. Supersensitive frequency meter—oblique front view

This frequency meter then consists of the tuning fork driven from the system frequency, and a vacuum-tube circuit measuring the phase angle between the system frequency and the resulting motion of the tuning fork. The accuracy of the tuning fork is so good that the over-all instrument accuracy depends only on the accuracy of reading the indicating instrument.

The marked scale of this frequency meter corresponds closely with the normal frequency band of a generating system, and each scale division is 0.005 cycle per second. Therefore, it will be seen that by estimating quarters of divisions, this frequency meter could be read to one part in 50,000. Thus, we believe that this development has brought the indicating frequency meter into a category which is comparable with master frequency methods.

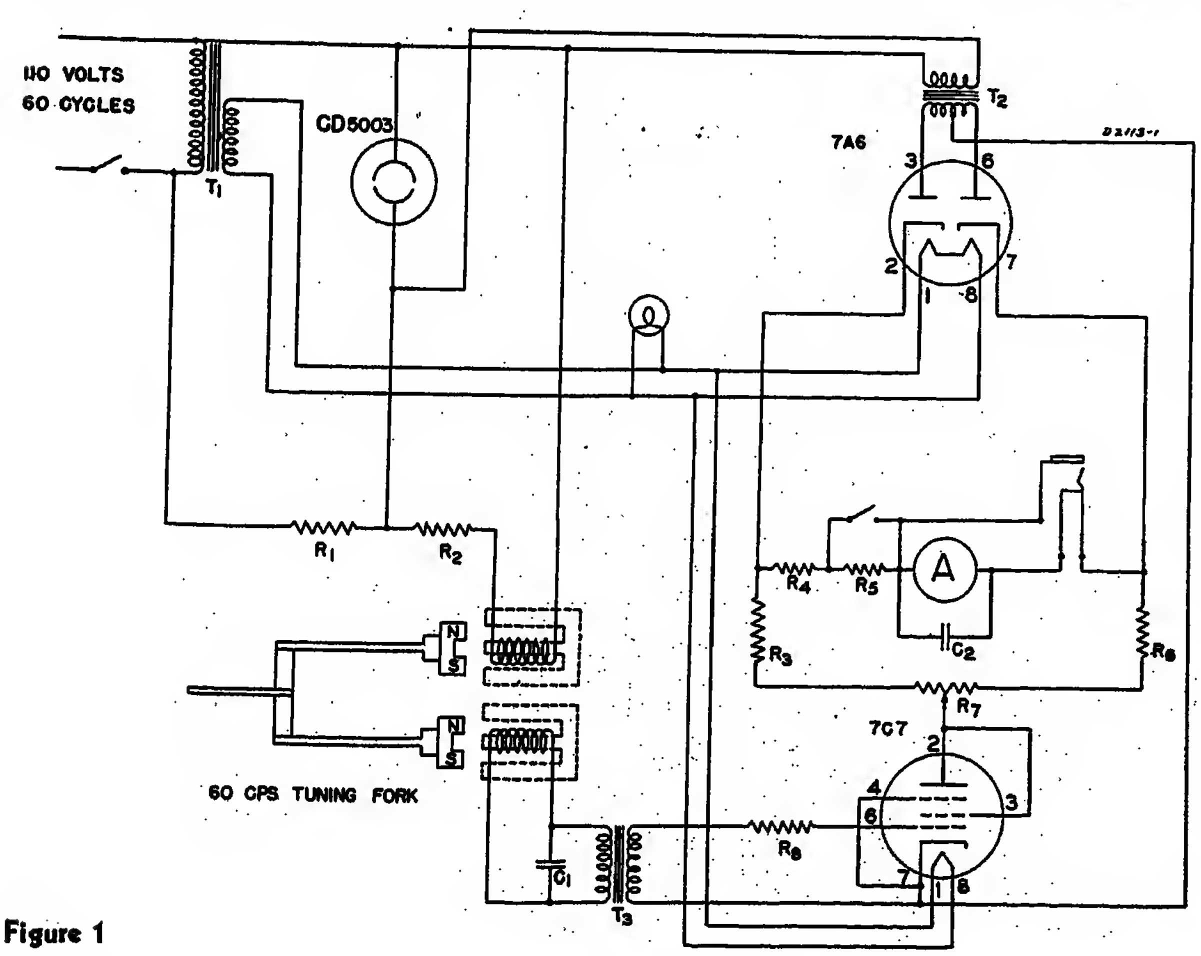

Figure 1

S. B. Griscom (Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa.): The authors have made an important contribution to the operating technique of interconnected systems. While some of the principles brought out have been appreciated for some time and have been incorporated in automatic controls, these have not been well understood by the operating personnel, nor were they particularly adaptable to manual control.

In the operation of a large interconnected system, it will always be necessary to exercise a certain amount of manual control or direction, no matter how refined the controllers nor how widespread their use. Load curves have a definite pattern on a given system, but vary with the day of the week and seasonally. Availability of generating capacity varies with maintenance schedules, rainfall, and unscheduled out-

ages, with individual station and system economy also playing a major role. Fitting these requirements together is the function of the system operator, according to flexible rules based on economy, reliability, and interchange contracts, all occasionally modified by contingencies.

The authors have shown that the best job of forecasting the system operator could do was not good enough if the orders were executed "woodenly." In other words, if a load drop was expected in a given area at a given time, this reduction should be ordered by the system operator, but not executed, unless it will tend to restore frequency to normal. With this procedure deviations from expected load changes will have a minimum disturbing influence on frequency and tie-line loadings.

Most of the control necessary for maintaining frequency and tie-line loadings can be done automatically, usually with advantage with respect to closeness of control, and with respect to freeing the operator from an onerous task. In addition to frequency and tie-line controllers, there is also available the "program load controller"[1] whereby the fluctuation in station output, instead of being taken by one machine, is distributed among all operating machines in the station, achieving the best possible thermal economy. This scheme has great practical value, as it relieves both system and station operators of continuous consideration of incremental thermal economy. The value of automatic control for any of these functions is, of course, dependent upon the rapidity with which load changes take place.

The stroboscopic means of showing each station operator visually the direction and amount of deviation from standard speed has much to commend it. In addition to permitting an improvement in manual control of load, it gives the operator a far better mental picture of cause and effect when manipulating the generator speed changers.

1. Tie-Line Control of Interconnected Networks, T. E. Purcell, C. A. Powel. AIEE Transactions, volume 51, 1932, pages 40–7.

J. E. McCormack and R. J. Lombard: The prime requisite for frequency control of load adjustments at generating stations is that the same indication of system frequency be presented to the operator at each station. This can be accomplished either by providing a standard frequency common to all stations and a suitable device for comparing with system frequency, or by individual frequency meters which have been compared for identity of indication and which will sustain their accuracy over a long period, regardless of atmospheric or other influences.

The instrument described by Hancock and Clark could be applied to frequency control of load swings, provided that it has the aforementioned characteristics and is suitable for use in generating stations. It appears to be a laboratory instrument with possibilities for conversion to a suitable operating meter if equipped with a readily visible scale and pointer, or possibly it could be adapted to provide the comparison standard for stroboscopic indication of frequency.

Mr. Griscom has taken this occasion to stress some of the problems encountered by load dispatchers and generating-station operators. Because of the innumerable situations that may occur in a station or upon the interconnections, automatic control must be supervised by the station operator and on occasion superseded by manual control. Automatic controllers relieve the operator of the labor of control, but the responsibility for correct operation remains with him. In view of this responsibility, he should have a thorough knowledge of system characteristics and be provided with sufficient information and adequate instruments for intelligent performance of his duties.

Series Capacitors for Transmission Circuits

Discussion and authors' closure of paper 42-112 by E. C. Starr and R. D. Evans, presented at the AIEE summer convention, Chicago, Ill., June 22–26, 1942, and published in AIEE TRANSACTIONS, 1942, pages 963–73.

J. W. Butler (General Electric Company, Schenectady, N. Y.): I have reviewed and studied this paper very carefully. My interest was greatly stimulated when reading the synopsis, wherein it was indicated there had been some new developments in protective equipments for series capacitors. My interest continued throughout the body of the paper, but I confess I was unable to discern just what new developments were being described. Therefore, I will outline my reasoning in order that my quandary might be appreciated—and I hope clarified.

Previous series-capacitor equipments in power lines utilized protective equipment fulfilling the requirements set down by the authors. The first series capacitor ever installed in a power line—described in reference 6 of the paper published in 1928—used such equipment.

Figure 1 of this discussion is an oscillogram dated 1935 showing the speed of operation of a protective equipment for a series-capacitor installation on a 22-kv circuit. This setup was adjusted so the closing of the contactor reduced the current sufficiently to cause it to open, which of course resulted in an increase in current making it close again, so it "pumped," closing and opening. It is seen that the contactor makes a complete round trip in $2^1/_2$ to 3 cycles, which is within the time intervals specified by the authors. For applications on long lines where some short-circuit currents can be relatively small, it may not be desirable to effect immediate reinsertion of the capacitor—as suggested by the authors—because of unnecessary operation of the protective equipment.

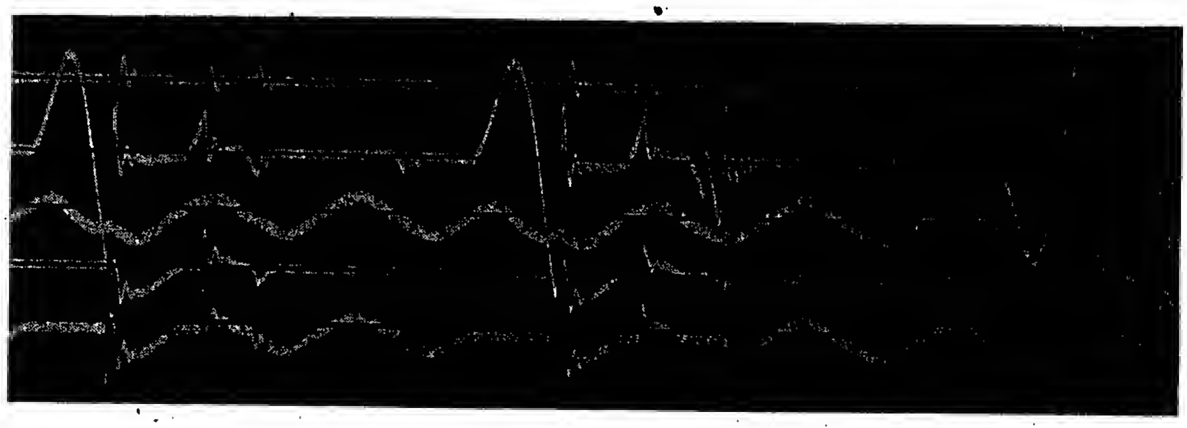

Figure 1

Therefore, I would like to ask: "What are the new developments that prompted the writing of this paper?" And in spite of the statement in reference 1 of the paper, I would like it explained why "previous equipments decreased rather than increased" transient stability.

The conclusion in respect to the necessity of suitable damper windings on machines to be operated with series-capacitor lines checks with our previous analyses and experiences. The following quotation is taken from June 28, 1941 *Electrial World*, in an article "Amortisseur Windings for Hydro Generators" by Crary and Dungan. "If series capacitors are used in the line connecting the machine with the system, the tendency for the generators to hunt may be aggravated to such an extent that amortisseur windings would be required."

The authors tested two motor-generator sets to determine the effects of damper windings. The basic criterion of the effects of a damper winding on machine performance is the effect the dampers have on the machine subtransient reactances and time constants. I wonder if the authors could give us these values for the two machines in question.

The ratio of the inertias of these units as given is about 4/1, the copper damper machine being the larger. Thus, I would expect its natural frequency to be about one-half the no-damper machine, but the measured frequencies show the copper damper to have approximately twice the frequency of the other.

Our previous studies agree with the authors' conclusion as to the location and arrangement of series capacitors. Figure 3 in reference 7 of the paper is remarkably similar to the authors' Figure 5.

S. B. Crary (General Electric Company, Schenectady, N. Y.): Over a year ago at the 1941 AIEE winter convention, Mr. Evans indicated he was in agreement with our conclusion of the value of series compensation over the other methods of improving the stability limits of long a-c lines. We are particularly glad to have this conclusion further substantiated in the paper by Starr and Evans. Such confirmation is important since it allows the emphasis to be placed on the details of how series

compensation may be best accomplished. In this respect, the paper by Starr and Evans is a valuable contribution, because it deals with those detailed questions which must necessarily enter into any practical application of series capacitors.

We have made studies of series capacitors somewhat similar to those reported in this paper. In 1928 a rather complete experimental test setup was made to check the stability of the system with and without series compensation for two and three synchronous machines. These tests indicated the safe limits of compensation and the degree to which the stability limits could be increased. Further analytical work has given additional quantitative information as to the limits of compensation. According to this work, the experimental results reported in the Starr and Evans paper indicate but one of the previously well-recognized boundaries of possible instability, that is, the hunting produced by large ratios of resistance to reactance in the transmission tie. As pointed out in a discussion by Concordia[1] there also exists a limit for the minimum amount of resistance that may be in the circuit. For practical systems this limit may be of greater importance than the one shown in the paper.

Our studies have also shown the advantages of placing the capacitors at the intermediate switching stations in the center section of the line where they will not be switched out with the line section.[2] Such an arrangement is desirable in order to reduce as much as possible the duty on the capacitor protective equipment.

Under "Types of Capacitors," the authors mention two kinds, the nonlimited- and the limited-voltage type, and indicate the desirability of using the limited type in order to reduce the cost of the capacitor. This is in general correct. However, it may be found desirable to prevent operation of the protective equipment for currents exceeding normal values and at least equal to those obtained during the largest angular swing at full-load which may be obtained without loss of synchronism. If the capacitors are capable of remaining effective in the circuit during such large angular swings, the over-all stability of the system will be improved for severe faults.

Under "Location in the Circuit" the authors point out there is little advantage in using more series capacitors than the number of intermediate switching stations. This statement is substantially correct when the switching stations are equally spaced along the line including the center portion of the line. The amount of compensation necessary is, of course, a matter of economics and performance characteristics. For a 234-mile line $66^2/_3$ per cent compensation reduces the equivalent line length from a reactance standpoint to 78 miles. Accordingly, such a degree of compensation for this length of line may not always be necessary but may be required for longer lines. The per cent compensation will tend to increase with the line length as well as with the amount of power it is desired to transmit. We would like to ask at what rate the required amount of compensation would decrease if the assumed transient stability limit margin were decreased. Since the economic study depends upon the assumed stability margin, this becomes an important factor for the application of series capacitors for improving the stability limits. It would appear that a 20 per cent transient-stability margin for the Grand Coulee system were unusually large if this were for the more severe type of transmission-line faults. Ordinarily a much smaller margin for the more severe faults may be used in the analysis, since the probability of obtaining these severe faults is itself small. Possibly the authors would explain in more detail why they elected to choose what seems to be a conservative transient-stability margin on which to base their economic study.

It has now become generally recognized that series compensation is entirely a practical and economic way to increase the power limits of long-distance transmission lines. The chief differences of opinion will probably arise from the assumed conditions of operation upon which their use is justified.

A. J. Krupy (Commonwealth Edison Company, Chicago, Ill.): There is one point which has not been mentioned by the authors in connection with the economic justification of the series capacitor as compared with the three-circuit alternative for the 230-kv transmission described in the paper. The cost figures as shown in the paper assume an equal degree of reliability for both schemes of power transmission either for normal or abnormal conditions. In my opinion such an assumption is not justified.

I would be interested to know whether the authors are in position to make a statement as to the relative degree of reliability of the schemes considered? It would also appear that under the existing conditions, the vulnerability of the single concentrated capacitance center both to an accidental electrical failure or an intentional mechanical damage, is much greater as compared with that of the conventional transmission circuit for the third 230-kv line.

Aside from the obvious difference in the inherent reliability of the two schemes, in the case of a complete outage of the newly added equipment or structure, the switching out of one half of the circuit shown in Figure 5c of the paper still leaves a superior system from the stability viewpoint as compared with as shown in Figure 5a, should there be an electrical failure or a mechanical destruction of the series capacitor.

A. C. Monteith (Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa.): The use of series capacitors to compensate for the reactance of transmission circuits has been recognized as a technical possibility for about 50 years. However, before such applications of capacitors could be put on a practical basis, a number of technical developments were necessary, including:

1. Reduction in cost and increase in reliability of capacitors.

2. Development of high-speed circuit breakers and relays for transmission circuits.

3. Development of protective equipment that permits the use of capacitors with voltage ratings determined by load currents.

The authors' investigation has established the practical aspects of the use of series capacitors so that the electrical industry should feel more confident in making applications.

We have heard much about the desirability of doing everything possible to conserve vital materials. Here is a scheme that accomplishes this desire at no sacrifice in system operating reliability.

E. C. Starr and R. D. Evans: In preparing this paper, the authors had in mind three principal elements:

1. Reactance compensation is economically sound when applied to appropriate major circuits. Voltage transformation results in line-resistance as well as line-reactance conversion. The most economic combination of impedance conversion and reactance compensation is desired.

2. The usefulness of series capacitors on transmission circuits is to improve transient stability. Application requirements of capacitors and protective equipment have been determined for a particular case, and the necessary functional arrangement for a protective scheme has been provided.

3. Systems with normal degrees of reactance compensation will not have impractical operating characteristics.

These views have been well supported by the discussion on the paper.

Mr. Crary's comment concerning our paper as a contribution, because it deals with the questions which must enter into any practical application of series capacitors, takes on added significance when it is realized that

1. Previous work was concerned principally with steady-state conditions, whereas the controlling stability condition occurs from transient disturbances.

2. Our paper not only presents the first theoretical analysis and miniature-system test results of series capacitors under transient conditions but also describes the combination of equipment necessary to make the scheme practical.

The reference quoted by Mr. Crary relative to the minimum as well as maximum amount of resistance that may exist in the circuit for stable operation indicates that for the typical case of a 230-mile line with 66.7 per cent reactance compensation, which was analyzed in the paper, the minimum stable length would be of the order of 75 miles and the maximum several times the assumed length. Consequently, the two limiting resistance conditions, as pointed out in this reference, are remote from the example given.

Mr. Crary has raised a question as to the selection of a particular margin of stability as the basis for the economic study. The choice for a selected stability condition must, of course, be based on experience in connection with the particular system and the judgment of the operating engineer. There are obvious advantages in having a margin above the calculated limit, since this makes operation less dependent upon fault-clearing speeds and upon the actual distribution of load and generating capacity. In answer to this question we have, however, made a comparison between the addition of a series capacitor and the addition of a third transmission line for the extreme increase in load which would eliminate all margin in tran-

sient stability for the same terminal impedances. Under this condition the first cost of adding the series capacitor would be about 40 per cent of the first cost of a third transmission line. If capitalized figures for additional loss and reactive kilovolt-ampere generation are added to the first cost of the capacitor, the series capacitor can still be installed for 75 per cent of the cost of adding the third line. It is to be emphasized that the economic study was made on a very conservative basis in regard to cost of construction and in regard to load factor which controls the capitalized figures for line loss. For this reason when the actual stability margin, line-construction cost, and capitalized losses are taken into account, the results, we believe, will be more favorable than shown in the paper. If the kilovolt-amperes of an individual generator is less than the rating of a line, added series capacitors can be proportioned to the particular case whereas added lines will come in relatively large steps.

Mr. Crary concludes his discussion with the statement that it is now generally recognized that series capacitors provide an entirely practical and economical way of increasing the power limits of long transmission circuits. This is a definite change in the point of view concerning the usefulness of series capacitors previously expressed in the AIEE TRANSACTIONS, volume 56, 1937, February Section, page 264, the pertinent excerpt from which is as follows:

"... To protect the capacitor against puncture the usual practice (in using series capacitors) is to use a normal voltage capacitor with means to short-circuit it during excess current conditions. The series capacitor as proposed is thus rendered ineffective at the time when it is most needed. The alternative is to use capacitors capable of withstanding the high voltages arising under fault conditions. In no major project in America has the series capacitor received serious consideration."

The foregoing was prepared by the AIEE subcommittee on interconnection and stability factors. Both Mr. Crary and Mr. Evans were members of this subcommittee and concurred in the views expressed. The change in viewpoint is believed to have resulted from the work reported in the present paper on economic gains and on transient stability with series capacitors. Previous articles, including items 7 and 8 of our list of references, have been limited to voltage-regulation studies and to steady-state stability conditions.

Mr. Butler's question of how series capacitors can reduce transient-stability limits and his request for more information on the protective scheme indicates a lack of understanding of the essential features of the series-capacitor scheme described in the paper. It is not sufficient merely to provide a series capacitor and means for short-circuiting it and subsequently restoring it to the circuit in response to the indications of a current-sensitive device. If a "protected" series capacitor is short-circuited upon the application of a fault, and if the fault is not quickly cleared and the series capacitor is not quickly restored to the circuit, the transient-stability limits will be reduced below the values which would obtain on the system without the capacitor in the circuit.

This condition results from the facts that

1. The excitation on machines will be slightly lower.

2. The initial angle between sending- and receiving-end machines will be slightly less.

Both of these conditions tend to reduce the transient-stability limit of the system with the series capacitors in comparison with the system without series capacitors. This viewpoint was back of the statement on series capacitors which was made by the AIEE committee on system stability and given in its report, an excerpt of which was previously quoted.

The essential features of a series-capacitor scheme for increasing transient stability have adequately been described in the paper. This scheme is based on using series capacitors of the protected type in combination with high-speed line-sectionalizing circuit breakers and relays. In this scheme the series capacitors are (1) short-circuited upon the occurrence of a fault which would produce excessive voltage and (2) quickly restored to the circuit after the fault is cleared, the combination functioning in a sufficiently short time to make a substantial improvement in transient stability over the value obtainable without the series capacitor. While the essential elements of the scheme are simple and easily understood, it involves a conception that is expected to make feasible the application of series capacitors for transmission circuits. Quite separate from this functional scheme are the details of the protective equipment. Space limitations made it desirable to omit the details of the protective scheme from this paper.

In general we are in agreement with the technical observations of Crary and Butler. However, the inaccuracy of Mr. Butler's characterization of the series-capacitor installation at Ballston in 1928 makes it necessary for us to point out that it was not an anticipation of the scheme described in our paper, because it does not meet the essential requirements of a scheme to increase transient-stability limits. Despite the complete mastery of the problem prior to 1935, certain misapplications of series capacitors subsequent to this date have placed the device in unfavorable light among some engineers.

We do not understand that Mr. Butler contends that either the protective equipment for Ballston or for the 22-kv installation which he mentioned is suitable for use with a 50-kv 100,000-kva capacitor installation on a 230-kv circuit, such as considered in our paper. Such a view of these protective schemes is consistent with the committee members' subsequent agreements to the statements on the limitations of protected capacitors from the standpoint of transient stability as given in the AIEE subcommittee report previously referred to. Such a view would also explain why no definite proposals of series capacitors for major transmission circuits have been made previously.

Mr. Butler has asked for additional information on the subtransient reactances of the miniature-system machines. The values are shown in Table I.

Table I. Subtransient Reactances of Miniature-System Machines

100-Kva Machine Damper	Reactance—Per Cent x_d''	x_q''
None	26.0	57.7
Connected copper	15.7	14.6

In reply to Mr. Krupy, we agree that there is probably more concentrated vulnerable equipment in the compensated two-circuit system than in the uncompensated three-circuit system. However, capacitors as now manufactured and provided with means for isolating a damaged unit should be essentially as reliable as switching or other terminal equipment and when properly installed should constitute no greater hazard to continuity of service than the more common equipment. They should be no more vulnerable to intentional damage than are generators, transformers, and circuit breakers.

The third circuit will under some abnormal conditions provide greater reliability, particularly if the third line is located on a separate right of way at increased cost. However, we should like to point out that the compensated two-circuit line can lose one section and remain stable under essentially the same loading as that for which the three-circuit line can lose one section and retain synchronism. If the two-circuit line loses both sections between the same switching stations, service will, of course, be interrupted. But if the three-circuit line similarly loses two sections between the same switching stations, the power capacity of the remaining circuit would be so low that if the line were loaded materially above 60 per cent of its rating, it would also lose synchronism and interrupt service. Consequently, as we view the comparison, the three-circuit uncompensated line has some advantage over the compensated two-circuit line under abnormal conditions, but, starting from normal circuit arrangements, their performance will be comparable for all of the more frequently occurring types of outages.

Mr. Monteith has outlined the steps in the technical developments necessary to put series capacitors for transmission lines on a practical basis. Consideration should be given, as he has suggested, to the conservation of vital materials made possible by this type of series-capacitor application. For the case considered in the paper the material required for the capacitor installation would be only a small percentage of that required for the third circuit.

Stability Study of A-C Power-Transmission Systems

Discussion and author's closure of paper 42-117 by John G. Holm, presented at the AIEE summer convention, Chicago, Ill., June 22–26, 1942, and published in AIEE TRANSACTIONS, 1942, pages 893–905.

J. A. M. Lyon (Ebasco Services Inc., New York, N. Y.): The author of this paper has made two useful contributions on the subject of stability:

1. Stability studies have been made on a variety of hypothetical systems including some with lines of great length and with operating voltages which in some cases are beyond those now in use.

2. The many well-known contributing factors to system stability have been listed and studied.

According to the author, equation 2 of the paper enables the transient stability of

a system to be found by comparison with a similar system of known transient-stability limit merely on the basis of the ratios of the reactances of the systems, the voltages, and the ratings of the systems. This relationship seems consistent with the factors affecting transient stability. However, it appears that the equation should be recognized as a means of obtaining an approximate result rather than an exact one. The ratio of system capacities does not seem capable of exact evaluation. The author's definition of system rating is too simple and requires further explanation. In the same way the author's claim that the expression is valid for systems of "similar configuration" is somewhat indefinite and should be explained further.

Figures 3 and 4 of the paper seem useful, but it is desirable to know if the author has checked either of these sets of curves by the known stability limits of actual systems which fall in the rather broad range of the systems of his computations. The curves of Figure 3 are called "estimating curves," and the range of usefulness should be proved as well as clearly defined.

Part II of this paper has indicated possible corrective measures to be applied to a system to increase the stability limits. The listing of these methods, together with the statement of the results of using some of these methods according to calculating board studies, seems valuable. Obviously the problem of improving the stability of a system involves many operating and economic considerations which the author has not discussed.

Upon reading the text on the use of reactors to increase stability limits it is not at all clear whether or not Figure 9 represents the increase of the stability limit due to the reactors alone or due to the reactors together with the larger generators required with reactors.

Many of the above comments have been in the nature of specific questions; the answers to these may very well increase the usefulness of the paper. The author should be commended for making available information on a large number of theoretical systems, as well as reviewing and checking many fundamental considerations of the stability problem.

S. B. Crary (General Electric Company, Schenectady, N. Y.): It will be realized by anyone familiar with stability calculations that the author of this paper has done a tremendous amount of work. He has made a worthy contribution by presenting the results of his study which include many of the factors entering into the transmission stability problem. This paper is concerned primarily with three methods of improving stability: intermediate synchronous condensers, generator bus reactors, and resistance grounding of the sending-end transformers.

All of these methods, as indicated by the author's references, have been considered, although no comprehensive study of their characteristics has been previously published. However, they have been carefully studied for particular systems. The conclusions, in general, which we have arrived at from these system analyses are:

1. The intermediate condenser for improving the stability limits of straightaway transmission lines is not so effective nor practical as the series capacitor which, in effect, reduces the equivalent line length.

2. Generator bus reactors have been found in general to be more expensive and less desirable as a means of improving the stability limits than the use of higher short-circuit ratio generators. Their use appears to be limited to stations which after completion have been found to have too low stability limits.

3. The use of resistance in the neutral of the sending-end transformers does provide a means for improving the transient-stability limits. The benefit from its use decreases with shorter switching time, higher generator inertia and is, of course, of no value for three-phase faults which are the most severe type. Accordingly, the use of resistance in the neutral may or may not be found necessary.

We would like to ask the author how he arrived at such a high value of equivalent reactance for the synchronous condensers (128 per cent). We would expect this reactance to be considerably less than this, particularly if the synchronous condensers are operating near full leading kilovolt-amperes.

F. Von Voigtlander (The Commonwealth and Southern Corporation, Jackson, Mich.): The author presents an unusually complete and readable paper on the subject of power-system stability. The premises on which the studies of the 31 assumed systems are based are of practical significance, and therefore the results are understandable and of value to those who must cope with stability problems in the industry. The reduction of the data to a series of tables and curves which can be interpolated and extrapolated for intermediate values is noteworthy and considerably extends the usefulness of the results.

Present conditions have greatly aggravated the problems of stability on many power systems because of the deferment of important system reinforcements and plant additions, upon which has been superimposed greatly increased war loads. These situations are a challenge to management to make the fullest use of the engineering ingenuity at its disposal so that the best possible service to essential loads may be provided by skillful disposition of existing facilities.

It therefore seems worth while to call attention to the fact that, in order to make full use of the potential stability limits of a power system, there are a number of factors to consider in addition to the power-angle relationships. Of these, the adequacy of protective relay and machine control systems is perhaps the most important.

High-speed fault clearance is most effective in mitigating stability troubles. Conversely, slow fault clearance can bring with it a host of complications. Unfortunately, slow fault clearance is quite prevalent, and often little can be done about it under present conditions, especially with older types of switchgear.

Practically all types of transmission-line relays may be subject to false operation during system oscillations, even within the theoretical stability limits of the system. The application of such devices should therefore be particularly well considered under these conditions. Auxiliary control devices may be required to assist in correct discrimination, for example, between an actual fault in a line section or the presence of an electrical center of oscillation there. In extreme cases, such correct discrimination may be impossible, even with the best equipment available, but often considerable improvement may be effected by comparatively simple rearrangements and minor additions.

Adequate control features for synchronous are also of importance, especially on condensers and on generators which may be motoring as condensers prior to the fault. Adequate excitation control and governor oil capacity may easily be the difference between success and failure of the system to ride through the oscillations incident to line faults, and again simple rearrangements, often within the scope of present restricted construction, can effect great improvements.

While the considerations of electrical and mechanical characteristics of machines, loads, lines, and switchgear are of fundamental importance in stability studies of electric-power systems, the application of controls to such equipment must be made with great care and with special emphasis on their behavior under emergencies so that they will permit the theoretical ability of the system to be actually attained. The practical power limits of systems may often be extended with only existing facilities by engineering ingenuity. Under the stress of the times, such efforts should easily be justified.

John G. Holm: The discussions presented do not lend themselves to a common reply; they will therefore be handled separately.

Mr. Crary prefers a series capacitor to an intermediate synchronous condenser for improving the stability limits of trunk transmission lines. It is true that the capacitor reduces the equivalent line length, but in the long lines the resistance is very large, and, if the line is to be economical, it will presumably transmit a large block of power, so that its current will also be high, even if the highest voltages are employed. Consequently the resistance drop is large even though it is assumed that lower-resistance conductors are justified economically. The longer the line, the larger the resistance drop which must be compensated by inductance, after allowing for some resistance to be left between the ends of the system. Therefore in the longer lines there will be a limit to the series-capacitor compensation that may be used, and consequently a limit to the increase in the stability limits obtained from this source.

It is embarrassing to disagree with a man of Mr. Crary's knowledge, but it seems to me that the series-capacitor compensation has definite advantages over the intermediate condenser only in lines from 150 to about 375 miles long, and no longer, assuming that the analysis of systems is made with actual loads and not on the basis of an infinite bus. However, so far as the economics of the question are concerned, it remains yet to be proved that even in 150- to 375-mile lines the advantage lies on the side of the series capacitor. So far, no economic comparison has been made between a line using series-capacitor compensation and the same line whose stability limits are raised to the same levels by the use of other means than the series capacitor.

As Mr. Crary points out, shunt reactors on the generator bus are more expensive than the higher short-circuit ratio of generators. So far as I know, the highest short-

circuit ratio of generators ever used is somewhere around 3.0, and it is very unlikely that the increase in stability limits obtained from this short-circuit ratio approaches that obtained from shunt reactors. Moreover, the short-circuit ratio has a far greater effect on the steady-state-stability limit than on the transient limit, and is to be resorted to primarily where the steady-state stability limit is to be raised first. The shunt reactors therefore may be used in addition to the increased short-circuit ratio in cases where the latter fails to bring the transient-stability limit to the desired level. The cost per unit of improving the transient stability by the use of the shunt reactor will therefore not be so expensive as might appear at first.

Besides the particular applications of the shunt reactor outlined in the paper, the shunt reactor, as well as the resistance in the sending-transformer neutral, is particularly well adapted for application to existing systems with prevailing slow fault-clearing times when it is desired to raise their stability limits. The resistance may, of course, be used if the transformer insulation is sufficient.

Mr. Crary asks why the synchronous reactance of synchronous condensers was taken at 128 per cent. In the first place, I wish to make clear that while the saturated synchronous reactance of the receiving-end condensers was taken at 128 per cent, that of the intermediate condensers was taken at 72 per cent (0.8 of the unsaturated value for both the receiving-end and the intermediate condensers). I regret that this figure was omitted from the second abridged draft of the paper. The unsaturated direct-axis synchronous reactance of synchronous condensers is given at 160 per cent in the First Report of Power System Stability and in other sources.[1–3] At any rate, it seems that the value of the synchronous reactance of the receiving-end condensers has a very slight effect, if any, on the system stability limits.

Mr. Lyon has asked a number of questions in his discussion. I regret that the limitations on the length of the paper did not permit going into the various details, and I am glad that the questions have been brought up. They will now be answered.

Equation 2 of the paper gives results within five per cent of those obtained by actual measurement on the network analyzer. By systems of "similar configuration," to which the equation applies, are meant trunk transmission lines. The number of circuits, the sectionalizing of the lines, or the lines, or the units of the end equipment are of no importance. As for the definition of the "system rating," I may say that much thought has been given to it. Whatever definition is given has only a theoretical significance, because for the two systems in question the quantity P enters the equation as a ratio, so that care should be taken only that exactly the same definition is applied to both systems. If the two transmission lines are designed on the same principles, so far as the conductor current-carrying capacity, corona power loss, and the voltage regulation are concerned; if the power factors and line and transformer efficiencies are properly taken care of; and if the transformer capacity is installed to fit the above conditions, in a similar manner in the two systems; then the installed transformer capacities may be taken for the quantity P. If the two lines are designed on entirely different principles, then either design correction factors must be applied, or what is known as the reliable rating of the line when there are no faults on it must be used. Care should be taken that criteria applied to both systems are as nearly as possible alike.

Mr. Lyon asks if curves of Figures 3 and 4 of the paper have been checked with stability limits of existing systems. There are very few systems whose stability limits have been reliably reported. The curves, however, have been checked on two systems, and a check was obtained well within engineering accuracy. The difficulties of such a check, however, should not be underestimated in view of the approximations necessitated by the network analyzer and the difficulties of evaluating and representing the system load. The stability limits determined on an actual system will never completely agree with those obtained through measurements on the network analyzer. The curves of Figures 3 and 4 are based on the study of a certain range of systems. They can be used for any fairly economical combinations of kilowatts, mileages, and voltages. When a case is taken of transmitting a certain block of power at a voltage entirely out of proportion to the transmission distance, a point on Figure 3 will be obtained which might lie either between the separate curves or entirely outside them.

Figure 9 represents the increase in the stability limits due to reactors with a corresponding increase in the kilovolt-ampere generator capacity, as discussed in the paper. I regret that this point was not made clearer. However, the increases in the stability limits due to reactors alone may be calculated by one of the methods outlined in the paper.

Mr. Lyon regrets that the paper does not discuss the economic considerations of the improvement in stability limits. There are so many factors entering into system costs that perhaps it would be desirable to present in a separate paper the costs and the effect on them of the various methods of stability improvement.

Mr. Von Voigtlander justly points out the importance of high-speed relaying and fault clearing of the transmission line. So far as system stability is concerned, there is nothing so effective as high-speed fault clearing. Mr. Von Voigtlander's statement that the system control equipment should be adequate for responding properly during emergencies as well as when the system is near its stability limits could not be made any stronger.

In conclusion I wish to thank the discussers kindly for the trouble they went to in preparing their discussions and for the contributions they made.

Analysis of Short Circuits for Distribution Systems

Discussion and author's closure of paper 42-88 by Charles F. Dalziel, presented at the AIEE summer convention, Chicago, Ill., June 22–26, 1942, and published in AIEE TRANSACTIONS, 1942, October section, pages 757–64.

F. S. Benson (Pacific Gas and Electric Company, San Francisco, Calif.): This paper is timely as a source of additional information for computing short circuits on low-voltage distribution systems when delta-wye or delta-delta transformer banks are installed, serving both three-phase and three-wire single-phase loads. The equations and formula developed in the paper will be helpful in determining the magnitude of short circuits on low-voltage or secondary systems.

I agree with the author that resistance plays an important part in limiting low-voltage line-to-ground short-circuit currents; all resistances should be included in the computation, even though they are of such low magnitude as bolted connections between wire and bar, or wire and wire. Field experience has shown that the magnitude of low-voltage line-to-ground short circuits is usually considerably less than that computed by ordinary methods; using reactance values only, we have found, if resistance is included, the computed values of short-circuit currents (line-to-ground) are in a reasonable agreement with those occurring in practice.

The graph in Figure 2 shows that the effect of ground resistance in limiting short-circuit currents is greatest at low voltage, that is, 800 volts or less, and is least when the transformer-bank secondary voltage is on the order of 12 kv. If, however, internal faults occur within such transformer banks, the effect of the ground resistance is quite important in reducing the magnitude of the line-to-ground voltage, even though the transformer secondary voltage may be as high as 12 kv. This is probably true because high-voltage systems are usually solidly grounded at the source of power and a transformer-bank internal fault adds an extensive zero-phase sequence network in series with low-voltage ground resistance.

The analysis of the magnitude of transformer reactance during transformer internal faults is interesting; the author's tests tend to confirm his conclusions that the transformer reactance can be entirely neglected when computing the value of such faults. The elimination of the transformer reactance from computations during transformer internal faults will aid in determining the correct and economical size of case ground wire or secondary-neutral ground wire to the grounding device.

Figure 16 is instructive and again substantiates my experience that ground resistances on the order of one ohm or less do not necessarily limit the rise of voltage on the transformer secondary neutral to the prevailing idea of a low value, when transformer internal faults occur. When distribution transformer banks are installed near substations having large power supply, and the ground resistance is a large propor-

tion of the total impedance to the fault, the voltage on the distribution transformer secondary neutral may approach the line-to-ground value of the primary voltage supplying the bank, although the ground resistance is considerably less than one ohm.

Charles F. Dalziel: The author is pleased to note that experience on actual power systems confirms the conclusions derived in the paper. This is significant, since all of the experimental data were obtained from tests made on small laboratory transformers operated at reduced voltage. The interpretation to the effect that, during transformer internal faults, the transformer may be neglected entirely, should be qualified slightly. As stated in the paper, it is believed that this simplification should give satisfactory results for cases in which the feeder impedance is at least equal to 50 per cent of the transformer impedance in high-voltage ohms. The change from solid to dash lines in Figure 16 indicates the proposed limit. The approximation may result in excessive error for transformers located near the bus. Obviously, neglecting the effects of the transformer would result in very serious error for transformers directly connected to a bus of maintained voltage.

Attention should be called to the fact that practical units are specified throughout the paper. Although per units may be used directly in most equations, corrections involving $\sqrt{3}$ are necessary when using per unit quantities in analyses involving unsymmetrical conditions in wye-delta transformations. This is true for the power-leg and light-leg equations derived in the paper, and practical units were specified to avoid introducing unnecessary complications.

Steady-State Theory of the Amplidyne Generator

Discussion and author's closure of paper 42-89 by Troy D. Graybeal, presented at the AIEE summer convention, Chicago, Ill., June 22–26, 1942, and published in AIEE TRANSACTIONS, 1942, October section, pages 750–6.

J. L. Bower and B. H. Caldwell (General Electric Company, Schenectady, N. Y.): The author has developed an interesting and useful method of predicting the characteristics of an Amplidyne generator with the aid of constants which can be measured from open- and short-circuit tests. We have been using a similar method, which is based on tests made on a large number of machines for a wide range of applications and have found in the general case that certain modifications of the theory presented by the author are required.

The author has confused speed-voltage coefficients with inductances. In general the author's terms L_{AA}, M_{A-s}, and so forth, which are speed-voltage coefficients, are not equal to the corresponding inductances, even though the units are the same. Also the mutual inductance between two windings is the same when viewed from either winding, while the mutual speed-voltage coefficient between two windings usually has different values when viewed from the different windings.

The steady-state equations 6 and 7 do not include terms which represent the speed voltage developed in the main- or direct-axis armature winding due to direct-axis armature current and the speed voltage developed in the cross- or quadrature-axis armature winding due to quadrature-axis armature current. These coefficients are primarily functions of the centers of current collection of the direct- and quadrature-axis currents. The effective center of current collection is a function of the brush position and all of the factors affecting commutation, such as magnitude of current, commutating field adjustment and brush characteristics (both mechanical and electrical) which vary with brush material, speed, commutator film condition, and so forth. Unsymmetrical spacing of the windings also gives rise to some degree of mutual coupling between all of the various windings, but experience has shown that for the normal case only the ones discussed above have sufficient effect to warrant their addition to the author's equations 6 and 7.

Adding the term $SM_{BB}i_B$ (the speed voltage developed in the quadrature-axis armature winding by current flowing in the same winding) and the term $SM_{AA}i_A$ (the speed voltage developed in the direct-axis armature winding by current flowing in the same winding), we obtain the steady-state equations

$$-i_A(R_A+SM_{AA})+i_BS(L_{AA}-M_{A-qB})=V_A$$

$$-i_AS(L_{AA}-M_{A-dA})-i_B(R_B+SM_{BB})+i_sSM_{A-s}=0$$

The open-circuit equations become

$$i_s=e_s/R_s$$

$$i_B=\frac{SM_{A-s}}{R_A+SM_{BB}}\,i_s$$

$$V_A=\frac{S^2(L_{AA}-M_{A-qB})M_{A-s}}{R_B+SM_{BB}}\,i_s$$

and the short-circuit equations are

$$i_s=e_s/R_s$$

$$i_A=\frac{S^2M_{A-s}(L_{AA}-M_{A-qB})i_s}{(R_A+SM_{AA}(R_B+SM_{BB})+S^2(L_{AA}-M_{A-dA})(L_{AA}-M_{A-qB})}$$

$$i_B=\frac{SM_{A-s}(R_A+SM_{AA})i_s}{(R_A+SM_{AA})(R_B+SM_{BB})+S^2(L_{AA}-M_{A-dA})(L_{AA}-M_{A-qB})}$$

and the load equations are

$$i_B=\frac{-S(L_{AA}-M_{A-dA})i_A}{R_B+SM_{BB}}+\frac{SM_{A-s}i_s}{R_B+SM_{BB}}$$

$$V_A=-\frac{(R_A+SM_{AA})(R_B+SM_{BB})+S^2(L_{AA}-M_{A-qB})(L_{AA}-M_{A-dA})i_A}{R_B+SM_{BB}}+\frac{S^2M_{A-s}(L_{AA}-M_{A-qB})i_s}{R_B+SM_{BB}}$$

The terms SM_{BB} and SM_{AA} appear in the same manner as the resistances R_A and R_B. These terms SM_{BB} and SM_{AA} can be and frequently are considerably larger than R_A and R_B. It is immediately apparent that the term SM_{BB} plays a very important role in determining the load characteristics; and since the coefficient M_{BB} is a function of load and speed, this variation instead of saturation and nonlinearity of brush drop, may well account for a considerable part of the curvature of the curves of Figure 8. Also the difference in characteristics with the different grades of brushes shown in Figures 6 and 7 might well be due to differences in commutating characteristics of the brushes rather than to difference in brush drop.

The author uses a negative sign in equation 5 before the speed-voltage coefficient, $SM_{A-qB}i_B$, which is the speed voltage developed in the direct-axis armature winding by current flowing in the stator coil in the quadrature axis. This is the convenient convention for the author's case, since the coil qB is assumed connected so as to partially compensate for armature reaction in the quadrature axis. Although the validity of the analysis is unaffected, it is of interest to note that in the usual case, particularly for small size machines, this winding is connected so as to increase the flux of armature reaction.

The author gives an appropriate summary of the difficulties involved in calculating the characteristics of the Amplidyne generator without the benefit of the constants which he determines experimentally. The designer must have the solution of this more difficult problem in order to build a machine which will have characteristics required by a specific application. However, as is often the case, the simplified method outlined by the author is a definite contribution toward the solution of the more difficult problem, since its use aids in the development and intelligent application of experience factors which simplify and improve the accuracy of the designer's calculations.

P. Lebenbaum, Jr. (General Electric Company, West Lynn, Mass.): The author is to be complimented on his analysis of the Amplidyne generator and the excellent check he has obtained between theory and test.

As has been pointed out, the Amplidyne generator is a dynamoelectric power amplifier. The three fundamental requisites of a good amplifier are its amplification ratio, its fidelity, and its speed of response. Commercial Amplidyne generators have calculated amplification ratios of 30,000 to 150,000 to 1, and time constants of less than one eighth of a second between signal current and output voltage. The time constant of the machine, while slow compared to the vacuum-tube amplifier, is nevertheless extremely small when compared with those of other machines in the circuits where the Amplidyne generator is most frequently applied.

The importance of good commutation and correct brush position in both short-circuit and load axes cannot be overstressed, for the brush short-circuit currents and magnetizing or demagnetizing ampere turns because of brush shift affect all three amplifier properties. The author's analysis assumes that the brushes are on the inductive neutrals in both axes and that the brush short-circuit currents are zero. If

these assumptions were not true, equations 4 and 5 would contain terms involving mutual inductances between the direct and cross axes, and succeeding equations would be changed. However, if the Amplidyne generator has been properly adjusted for commutation with all brushes on their respective neutrals, these additional terms are not needed in the steady-state analysis.

An example of the importance of brush short-circuit currents is the author's test shown in Figures 6 and 7. The difference in saturation curves of the experimental Amplidyne generator because of change in cross-axis brush material is due as much to change in cross-axis brush short-circuit currents as to change in brush drop. The experimental machine was apparently compensated properly with the soft graphite brushes in place, for the curves of Figure 7 agree closely with theory, the open-circuit voltage varying approximately as the square of the speed for constant signal current. However, the change to a harder brush, while keeping the same compensation in the commutating field, results in undercompensation of the coils undergoing commutation. It can be shown that undercompensation in the cross axis results in a directly demagnetizing effect in the signal field axis. The higher the speed, the higher are these demagnetizing ampere turns. Thus the open-circuit voltage no longer varies as the square of the speed, and hence the "crowding" and nonlinearity of the curves of Figure 6 results.

Troy D. Graybeal: The discussions by P. Lebenbaum, Jr., J. L. Bower, and B. H. Caldwell are both pertinent and interesting. The representative data for commercial Amplidyne generators given by Mr. Lebenbaum are particularly significant.

Concerning the addition to the equations of the two speed terms which represent the voltages generated in either axis of the machine by current in the same axis, these terms theoretically should be included if a more accurate solution of the steady-state operation of the machine is desired. However, the apparent increase in accuracy cannot be realized in actual practice, because the coefficients M_{BB} and M_{AA} are critically dependent upon the condition of the brush contact surfaces, as well as upon the brush position. For example, the slight "play" between ordinary brushes and brush holders will cause a large increase in these constants when the direction of rotation is reversed. A slight shift of the brush position from the true neutral, or a slight change in the surface conditions, because of the minute arcs between brushes and commutator caused by normal load current, might make the coefficients several times larger. Figure 1 shows the values of ohmic resistance and of SM_{BB} plotted against speed. The two nearly linear curves show that while M_{BB} was constant for each test, a change in cross-axis current changed the value of the "constant" by a factor of four. This increase was due to the change in the distribution of current over the brush surface, even though no change had been made in brush position or commutating pole adjustment.

For the calculation of the curves given in the paper, an average of the cross-axis circuit equivalent resistance was taken as shown by the dotted curve of Figure 12 of the paper. The actual ohmic resistance was 1.16 ohms, which was increased to 1.55 ohms to give the equivalent resistance used for the calculations. This procedure is justified by Figures 10 and 11 of the paper which show that the curves calculated on this basis do give a very close approximation to actual test results.

The theory presented in the paper was developed by calculating the speed voltages which are generated in the armature of the machine. The coefficients which appear in the final expressions are ratios of flux linkages to currents and therefore are coefficients of inductance. These coefficients would be identical with the open-circuit inductances if perfect commutation could be obtained in the exact geometric neutral. The fact that these conditions cannot be fulfilled in an actual machine gives rise to effects which reduce the output of the

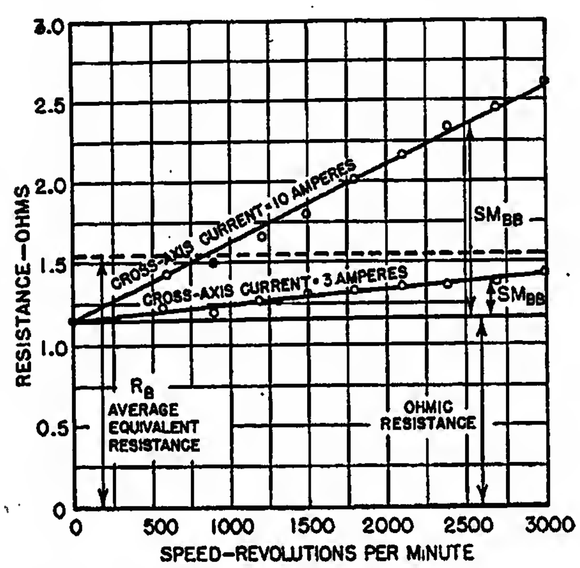

Figure 1. Curves showing the components of the equivalent cross-axis circuit resistance of the Amplidyne generator and the variation of these components with speed

machine. Actually, these effects represent a reduction in the numerical values of the coefficients of inductance compared with those obtained from measurement with the coils open-circuited and the brushes of the machine raised. The fact that the performance of the Amplidyne generator cannot be calculated on the basis of inductances obtained from the usual methods of calculation or from usual inductance test procedure does not mean that the coefficients which appear in the equations are not inductances, but rather that the inductances are different under actual conditions of operation. These differences arise because the distribution of flux is not the same as is usually assumed for calculation, or as that which exists during open-circuit inductance measurements. Since Bower and Caldwell prefer to call the coefficients which apply in actual operation "speed-voltage coefficients" rather than inductances, no doubt they find that this terminology avoids confusion in their work with Amplidyne generators.

The negative sign mentioned was used in equation 5 because the flux of the commutating pole in the cross axis always opposes the flux of armature reaction. If in addition an additive coil in the cross axis is used in an attempt to increase the cross-axis flux, only a slight increase can be obtained. The additive turns increase the resistance of the cross-axis circuit and therefore decrease the current. This smaller current flowing through the increased number of magnetizing turns produces only a slight increase in flux. The additive coil will increase slightly the machine efficiency and also tend to mask out the nonlinear effects introduced by the brushes, the commutating voltages, and so forth, in the cross-axis circuit. On the other hand, omission of this coil will improve the speed of response of the Amplidyne generator to changes in the signal current.

The purpose of this paper was to present the theory of the Amplidyne generator in a form suitable for use in applying the generator to control mechanisms. For this purpose, simple expressions of the operation are essential, because the Amplidyne generator must be studied, not as an isolated unit, but in relation to all other units of the control mechanism. Information on details of design can be obtained from tests of experimental machines; these "experience factors" are helpful to the designers but are seldom published, and therefore are not available to the purchaser. It is hoped that this paper will encourage the publication of the results of other investigations which no doubt have been made upon the Amplidyne generator.

Precision Speed Control for World's Largest Induction Motor

Discussion of paper 42-132 by R. R. Longwell and M. E. Reagan, presented at the AIEE summer convention, Chicago, Ill., June 22–26, 1942, and published in AIEE TRANSACTIONS, 1942, September section, pages 634–8.

E. Herzog (U. S. Army Air Corps, Wright Field, Dayton, Ohio): A few explanatory notes may be in order in regard to the authors' presentation of this particular control problem.

Essentially two controls, the start–stop switch and the speed setting, permit the operator to control the entire assembly in normal operation. The one brings the fan motor to standstill, ready to run, or shuts it down from that point; the other controls it through the entire speed range from standstill to maximum speed. As long as the equipment performs properly the operator merely supervises the correct functioning of the control. The total investment in the installation is, however, so great, and the need for its use so urgent at certain times that the drive could not be held inoperative because of a failure of the automatic control. For this reason control can be transferred from automatic to manual at any point in the operating cycle. To facilitate repairs after completion of the run, the control can be rapidly subdivided and reassembled in various groupings.

With modern tendencies toward automatic control there may be no need to explain the particular set-up, but the authors pointed out the elaborateness of the con-

trol, and, as has been stated in this discussion, the control is in some respects only semiautomatic.

The large investment in the equipment is obvious. The new type of equipment precluded the possibility of using operating personnel familiar with its operation, and the enormous expansion of the plant made it most improbable that trained operators could be obtained in the present state of the labor market. The expectations were actually fulfilled; trained personnel have to be scheduled carefully for key positions. The automatic control described has made it possible to operate equipment of considerable complexity with a minimum of trained personnel leading a large group of semitrained employees. The government engineers specified the control requirements, and the co-operation of the electrical industry has been most gratifying in this and many other cases when it has been necessary to fulfill unusual requirements.

Electrical Features of Design and Operation of the Plantation Pipe Line

Discussion and author's closure of paper 42-143 by M. A. Hyde and H. B. Britton, presented at the AIEE summer convention, Chicago, Ill., June 22–26, 1942, and published in AIEE TRANSACTIONS, 1942, September section, pages 638–44.

W. E. Stueve (nonmember; Oklahoma Gas and Electric Company, Oklahoma City, Okla.): Since I have been interested in the electrification of crude oil and oil-products pipe-line pumping stations for a great number of years and have conducted negotiations for my company resulting in the complete electrification of certain transcontinental crude-oil pipe lines, I was given an opportunity to discuss this paper by the authors.

I think the engineers are deserving of the highest praise in working out the design of the motors used in the pump stations, which design enables the operators to increase the motor output 50 per cent by merely increasing the ventilation or air-cooling arrangement of the motor. Thus, on the 12-inch section of the line 600-horsepower motors are used for original capacity, and the same motors will deliver 900 horsepower later on, after the intermediate booster stations are installed. This problem always arises in most crude-oil pipe lines being installed to handle the flush production of newly discovered oil fields.

Another contribution, which the design electrical engineers have made to the pipe-line industry, is the recognition they give to high load factors or capacity factors at which most pipe-line pumping stations operate. The motor is designed for low starting torque since the centrifugal pumps are always started against a closed header gate valve with consequent low rotor resistance, resulting in very good efficiency of the motor itself.

Another achievement accomplished by the design engineers is the elimination of a fire wall between the pump and motor. Most early-day pipe-line operators were reluctant to install electric motors for pump station use on account of the apparent fire hazard. The elimination of the fire wall reduces the investment in the pump station which tends to make the use of purchased power more economic.

The automatic control features embodied in the design of the pump stations are also an achievement of note, since they eliminate the human element to a great degree in the operation of the pump station. Certain labor savings are thereby accomplished which again tend to make the use of electric power more economic.

The only criticism I would care to offer is one of a mechanical nature perhaps but which has to do with the over-all flexibility in the pumping operation. In my experience in negotiating contracts for pump-station electrification, I was always confronted with the statement of manufacturers of other forms of prime movers that, since the electric motor speed could not be efficiently changed, and the induction motor was essentially a constant-speed prime mover, it did not offer the proper flexibility, when changes in capacity were desired. This operating flexibility was discussed very briefly by the authors, but in my judgment this should have been enlarged upon to a greater degree by showing what actual capacities could be achieved at high efficiency points of both motor and pump in a long pipe line similar to the Plantation Pipe Line containing a great number of pump stations. Thus, as an example, if we assume a level pipe line employing four pump stations with two pump units in each station arranged in series, the following capacity rates can be realized:

Eight pump units or all motors on this hypothetical line, of course, will provide 100 per cent capacity; six pump units, properly selected, will provide 86 per cent capacity; and five pump units, properly selected, will provide 78 per cent capacity. One pump unit in each station will provide 70 per cent capacity. Intermediate values of capacity between those selected above can be achieved by throttling the discharge to a certain extent without lowering the pump or motor efficiency very much.

As stated previously, the dual horsepower design of a motor, permitting the increased loading of the motor or decreased loading of the motor, as the case may be, is an outstanding achievement, for in the case of crude-oil pipe lines the loads are always greater at the outset, because of the flush oil production being handled with a resulting decrease in capacity later on. In the case of gasoline or oil-products pipe line the reverse is true, in that the original capacities are low until the business is built up, and as more capacity is required the larger loading of the motor becomes necessary. All of this eliminates tearing out motors and purchasing new equipment as time goes along, and this design accomplishes results by merely adding or taking off a fan on the rotor to increase or decrease the ventilation.

M. A. Hyde: It is of interest to note that the provisions made in the original design of the line for capacity increase already are justified. Since the paper was written, it has been found desirable to increase the capacity of the main line, and fourteen new intermediate stations are now under way, which will provide 50 per cent more throughput. When this work is completed, the aggregate motor horsepower on the system will be 51,000 horsepower.

Analytical Treatment for Establishing Load-Cycle Ratings of Ignitrons

Discussion and authors' closure of paper 42-94 by D. E. Marshall and E. G. F. Arnott, presented at the AIEE summer convention, Chicago, Ill., June 22–26, 1942, and published in AIEE TRANSACTIONS, 1942, August section, pages 545–8.

O. K. Marti (Allis-Chalmers Manufacturing Company, Milwaukee, Wis): In their paper, the authors D. E. Marshall and E. G. F. Arnott, have solved in a very clear and practical way the problem for rating of rectifier tubes subjected to different load cycles, but by doing so they have considered only their thermal characteristic and acceptable arc-back frequency as the limiting factor.

During the last two years, the Allis-Chalmers Company has been conducting field as well as laboratory investigations in order to determine the influence of the inverse current on arc-back frequency. It was found that the arc-backs are in a certain relation to the inverse current and that this current is an important factor for determining the rating of rectifier tubes. In most cases it is possible to cool the rectifier in such a way that no internal parts of the tank or tube reach a critical temperature. However, it is not so simple to arrange the baffling in

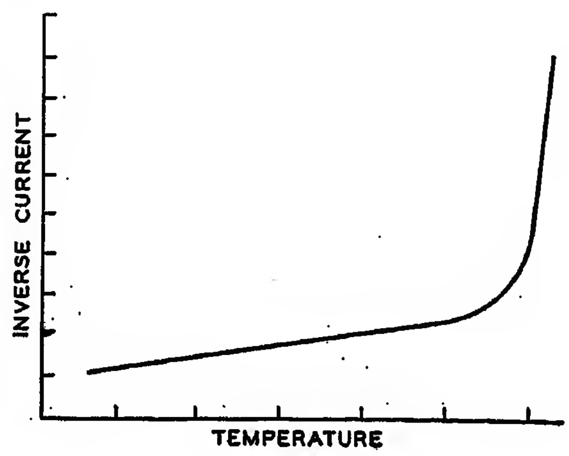

Figure 1

order to limit to a certain degree the ionization during the inverse cycle or the inverse current without introducing disturbing arc phenomena. Therefore, besides the temperature of the cooling water, the deionizing properties of the tube also will have to be taken into account. This means that the inverse current, which is no doubt responsible for terminating the length of life of the tube, has to be considered when rating a rectifier.

As can be seen in Figure 1 of this discussion, after a certain temperature the inverse current increases very rapidly and may reach a value which can endanger considerably the life of some internal parts of the tube. It is therefore necessary, when

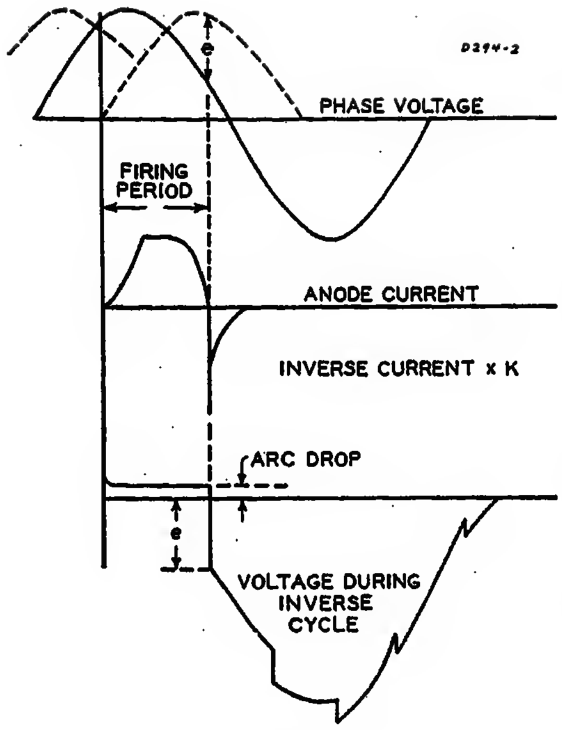

Figure 2

attempting to rate a tube, first to determine the temperature at which the inverse current does not exceed a certain safe value, and only then is it advisable to employ an analytical treatment such as outlined by the authors. The backfire test, as outlined by the authors, is no criterion for the rating because at higher d-c voltage the backfire frequency is not only a function of the cooling (or of the inverse current) but also of the anode voltage during the inverse cycle, especially of the value following the firing of the anode. (See *e* in Figure 2 of this discussion.) In other words, the inverse current of a given tube is a function of the cooling as well as of the voltage impressed between the anode and cathode during the inverse cycle.

In case a tube is being used in a welding circuit, or a six-phase rectifying circuit, it will have to be realized that for the same temperature of the tube a considerable difference in the backfire frequency may be found, due to the difference of the negative voltage (e) at the end of the firing period.

For instance, a curve illustrating backfire temperature against anode current, as shown in Figure 4 of the paper on "Sealed-Tube Ignitron Rectifiers" by M. M. Morack and H. C. Steiner holds good only for the circuit used during this test, and therefore, the rating cannot be based on the level of load which the tube will carry with acceptable backfire frequency.

In order to obtain very definite operating and rating characteristics for a given tube, it will therefore be necessary to take into account the above considerations regarding the current and voltage during the inverse cycle.

D. E. Marshall: Mr. Marti has offered several interesting and pertinent remarks concerning methods to use in determining the basic rating of a mercury-arc rectifier. We are, in general, in agreement that among other things the arc-back rate should be a function of the inverse current and the wave form and magnitude of the inverse voltage. In fact, our paper is actually based on such an assumption. We assume, that, for a given magnitude of inverse voltage at a given wave form, the other variable factors influencing arc-back are the demand current and the pressure of mercury vapor. The latter two determine the inverse current. Experiments performed in the Westinghouse Electric and Manufacturing Company on an unshielded ignitron a number of years ago indicate that for a given water temperature the inverse current is a nearly linear function of the demand current, other factors being constant.

In welding control circuits, the inverse voltage wave form depends on the line voltage, the power factor of the circuit, and the degree of phase control. Sealed-off ignitron tubes are rated for the worse combination of the above factors. This determines the voltage wave form. The current wave form is also set by the above setting of power factor and phase control of the test circuit. Thus the transition voltage is definitely set, and the rate of change of load current is directly proportional to the magnitude of the demand current. The water temperature is set at the maximum rated temperature.

Under the above conditions, the problem of rating the tube reduces to specifying the magnitude of the demand current allowable for a given duty cycle.

Our method assumes that the probability of arc-back at a given duty cycle will not exceed that of the basic test if the equivalent temperature of the vapor between anode and cathode does not exceed that of the basic test. This, we assume, will be the case if the heat energy stored in the tube structure and vapor never exceeds that stored in the basic test. We further assume that the stored energy is equal to the tube loss minus the heat carried away by the water and air-cooling facilities of the tube.

This would seem to agree with Mr. Marti's comments as follows:

1. The inverse current will be directly proportional to demand current.

2. If the arc-back rate is proportional to inverse current, then by item 1 it is proportional to the demand current.

3. Since, in general, the number of arc-backs that can be tolerated is measured in elapsed time and not in actual conduction time, then it would seem that the product of conduction time and demand current should be made constant. This means that the average current in the tube should be constant. This conflicts with the original assumption that the maximum equivalent vapor temperature be not exceeded. However, if the equivalent vapor temperature is kept constant, the average current criterion is within safe limits.

Mr. Marti's comments regarding rectifier operation as directed to the paper by Morack and Steiner are well taken in that the following factors need to be specified when the quality of performance of a given rectifier tube is judged.

1. Type test circuit.

2. Type load: Resistive; Inductive; Counter electromotive force

3. Inverse voltage wave form.

4. Rate of change of anode current at commutation.

The preceding four factors are interrelated and can be specified quite accurately by specifying the type circuit, the regulation, phase control, and loading.

Material for many papers could be found in the thorough investigation of the effect of circuit constants on the reliability of rectifier operation. It is hoped that these discussions will stimulate further research along this line.

Sealed-Tube Ignitron Rectifiers

Discussion and authors' closure of paper 42-106 by M. M. Morack and H. C. Steiner, presented at the AIEE summer convention, Chicago, Ill., June 22–26, 1942, and published in AIEE TRANSACTIONS, 1942, August section, pages 594–9.

O. K. Marti (Allis-Chalmers Manufacturing Company, Milwaukee, Wis.): This paper outlines a very interesting account of the development which has taken place during the last few years in connection with sealed-off single-anode Ignitron type of rectifiers.

I would like to point out that a practically backfire-free operation and a low arc-drop single-anode rectifier can also be obtained when using a continuous ignition-excitation system, in spite of the fact that a cathode spot is maintained during the inverse cycle. In other words, it is not necessary to use an ignitor for initiating a cathode spot every cycle in each tank. Operating experiences with the Allis-Chalmers "Excitron" rectifier with a continuous ignition-excitation system have definitely proved that the small excitation arc does not increase deionization during the inverse cycle to such an extent that it contributes to the arc-back susceptibility.

I had occasion to call attention to this fact in my paper "Excitron" rectifiers, presented during the 1940 winter convention of the AIEE.

A cross section of a rectifier tank with continuous excitation, as introduced by the Allis-Chalmers Company over three years ago is shown in Figure 1A of the paper. This tank is somewhat larger than the one shown by the authors in their Figure 2 but is about equally shielded. A unit with six such tanks was in operation for several months on 600 volts and finally went into operation, supplying load to an industrial plant at 250 volts, 2,000 amperes, with occasional overloads of up to 3,000 amperes. This unit has been carrying such loads for over a year without a single backfire, in spite of the fact that the shielding is very slight, having a grid with relatively large holes. This particular "Excitron" rectifier tank had an arc drop comparable to that of the "Ignitron" rectifier, even at a lower current, that is, up to the current rating of the ignitor tube. This may show that the "Excitron"-type rectifier does not require more deionizing properties in spite of the fact that the excitation fires over the whole cycle. Naturally no difficulty is encountered in building a sealed-off rectifier tube using the continuous ignition-excitation system.

The use of two ignitors and a holding anode as shown in Figure 1 of the authors'

paper complicates the design of the Ignitron rectifier and also requires a relatively complicated circuit with considerable auxiliary equipment. We would like to know if the authors consider such complication of the ignition-excitation system necessary only in connection with rectifiers used in the industrial and railway field, where the load fluctuates greatly and where periods of very low loads are encountered. Furthermore, does the introduction of a holding anode reduce the arc drop and the surges at low temperature?

Under the heading, "Ignitor-Excitation," the authors refer to a rather serious limitation, which is encountered during low load periods with the ignitor system. It may be of interest that the previously referred to "Excitron" unit was for several months operating on very low load, sometimes in parallel with a motor-generator set or convertor, but no difficulties were encountered in carrying loads of a few amperes.

REFERENCE

1. "EXCITRON" MERCURY-ARC RECTIFIERS, O. K. Marti. AIEE TRANSACTIONS, volume 59, 1940, pages 927–31.

J. H. Cox (Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa.): I was happy to note the statement in this paper regarding the relationship between arc-drop and arc-back frequency in any given type of mercury-arc rectifier. This relationship exists in all types of rectifiers and should be recognized.

In Figure 3 of the paper it is noted that the arc-drop curve of the Ignitron described is plotted in terms of instantaneous anode current. In general, the user of rectifiers is interested in the arc drop in terms of cathode current. I would like to ask whether the authors find that the cathode current per group may be applied to this curve or if the average arc drop is influenced by the various rectifier transformer connections because of the difference in the length of the conducting period. In general, the arc-drop voltage is higher at the beginning of a conducting period, before maximum ionization density has built up, and this would suggest that those circuits utilizing the shorter conducting periods would have somewhat higher average arc drops. My own experience indicates that the difference is negligible.

I was interested in the authors' statement that the Ignitron described does not exhibit surging characteristics down to a cooling water temperature of the order of ten degrees centigrade. In general, Ignitrons are much superior to multianode rectifiers from this point of view, because of the short arc length and small amount of shielding. In our experience with pumped-type Ignitrons we have never found any instability in the arc, with suddenly applied loads up to 300 per cent rating at water temperatures as low as six degrees centigrade, the minimum water temperatures available in Pittsburgh in the wintertime.

In Figure 5 the authors indicate double two-phase circuits for the utilization of four tubes. All multiple-group rectifiers require interphase transformers and enough inductance in the load circuit to maintain multiple-group operation. The advantage is a more effective use of the transformer windings and lower maximum currents in the anodes. In the case of six tubes the advantages far outweigh the disadvantages. However, in the case of double two-phase operation, the disadvantages become greater and the advantages less. A straight four-phase transformer is definitely no larger than a double two-phase with interphase. The lowering of anode duty is not so great as in the six-tube case. The operation of a double two-phase rectifier is definitely more critical, and the simplicity of the straight four-phase circuit has much in its favor.

The figure of 100 watts per ignitor for the Rectox-charged capacitor excitation circuit seems low, and I believe that 200 watts would be more nearly correct.

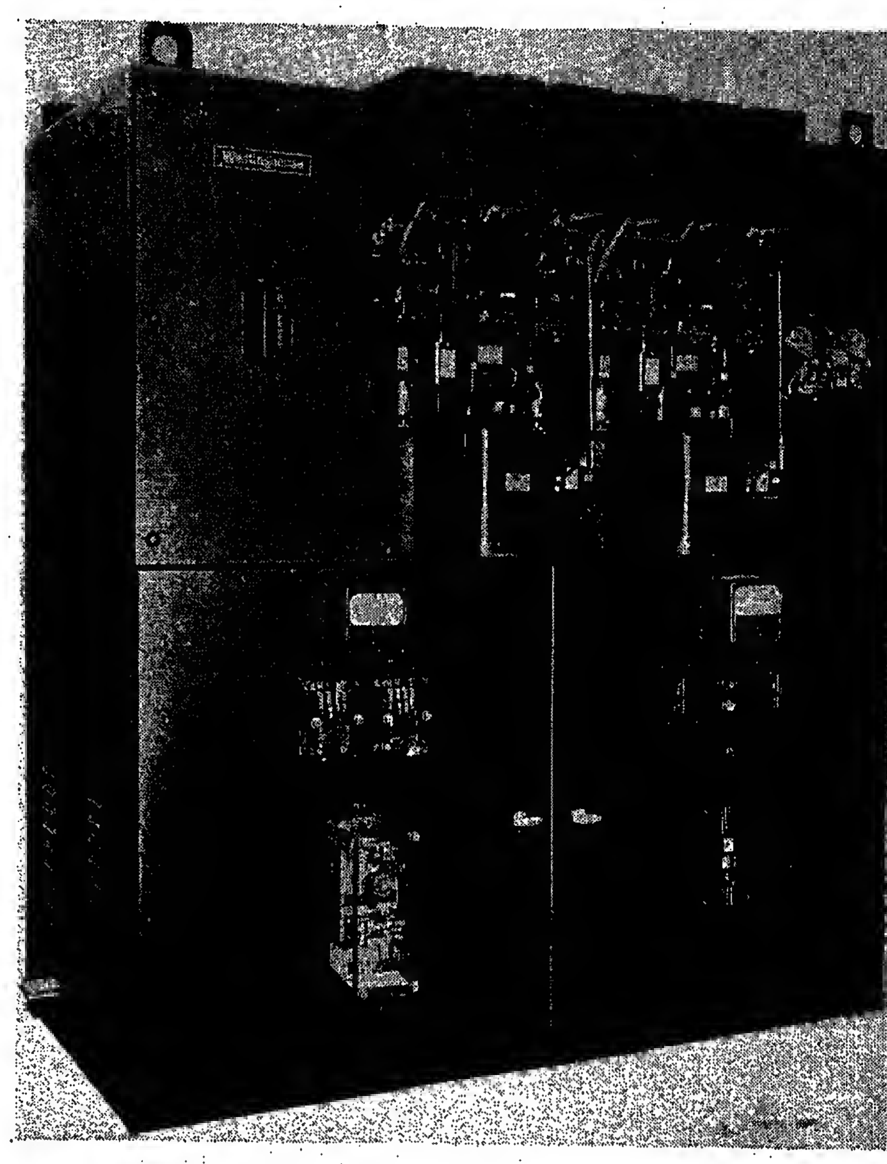

Figure 1. Sealed-off Ignitron assembly

I do not agree with the statement that fuses for the interruption of arc-back currents are satisfactory. We have hardly arrived at the point where arc-backs are so rare that the inconvenience of fuse replacement for every arc-back would be negligible, and in view of the relationship between arc-drop and arc-back frequency, I do not think that such a low arc-back frequency would be desirable. I believe that the simplest and most attractive over-all arrangement for these small rectifiers is the use of disconnecting fuses in the primary circuit of the rectifier transformer and anode breakers in the secondary circuit of the transformer with only a disconnect in the cathode circuit. Such an arrangement provides the most complete protection, since modern air breakers are considerably faster than oil breakers, and by the use of anode breakers maximum protection is provided both for the rectifier and for the associated transformer.

By the use of anode breakers the complete switchgear, with the probable exception of the primary disconnecting fuses, can be mounted in a cubicle with the rectifier and the a-c switchgear unit shown by the authors in their Figure 10 can be eliminated. Figure 1 of this discussion shows a sealed-off Ignitron assembly in which the complete switchgear, with exception of the primary disconnecting fuses, is included.

The authors indicate, and suggest, the use of raw water directly in the Ignitron tubes. In many cases the cooling water available is such that trouble is encountered with scaling and deposits which interfere with water flow. Furthermore, best sealed-off Ignitron-rectifier operation is obtained with a high water rate, and such a rate is not possible with the circuits shown in the authors' Figure 13, unless temperature control is abandoned and water consumption prohibitive. Of course, by the addition of a pump, the raw water can be recirculated in a local path and still retain direct water cooling with high velocity and control.

In many of the authors' statements they give figures of efficiency and losses without mentioning the voltage of the application. I assume that in all these cases they are discussing 250-volt rectifiers.

M. M. Morack and H. C. Steiner: Mr. Marti's experience with the continuously excited single-anode mercury pool rectifier is very interesting. As Mr. Marti points out and as stated in the paper summary, it is the single-anode design with its low density of ionization during the inverse cycle which reduces the shielding necessary to prevent arc-back and thus lowers the arc losses.

In considering the method of cathode-spot excitation, the principle of igniting the spot each cycle offers two advantages:

1. With continuous excitation it is necessary to provide some form of cathode-spot stabilization or, as shown in the cross section of the Excitron tube, to insulate the pool in order to prevent the arc leaving its surface and anchoring on the tube walls.

2. It is felt that phase control of the output voltage is essential in the sealed type of rectifier.

The ignitor provides these functions with a minimum of complication in the design of the tube itself. Control of the ignition impulse serves the dual purpose of ignition and phase control.

The addition of a second ignitor is simply insurance. Actually, experience indicates that the ignitor is a very reliable device. Failure is more often due to abuse or misapplication, or lack of understanding its characteristics than anything else.

The holding anode was added as a result of field experience which indicated that minimum load conditions were likely to be encountered in sets of relatively high current capacity. Its addition did not change appreciably either the arc drop or surge conditions.

The arc-drop data in Figure 3 were determined in a three-phase single-way circuit using a vacuum-tube amplifier and cathode-ray oscillograph. The data are the average of the voltages at the beginning and end of the full-current conducting period. The arc drop is roughly a volt higher at the beginning and a volt lower at the end, when there is an excess of ionization. It would seem, as Mr. Cox suggests, that the arc drop should be higher in circuits with shorter conducting periods. However, our experience indicates that the difference is negligible.

In regard to the circuit, we believe that circuits of the multiple type with interphase are preferable because of the greater transformer utilization and lower tube arc losses. Our experience indicates that the double two-phase circuit is fully as stable as the double three-phase. The control is particularly stable since the average output voltage is the same at light load and 90 degrees phase control (four-phase operation) as at full load with 0 degrees phase control (two-phase operation).

The excitation loss in the capacitor circuit was determined by wattmeter measurement. The measured loss, including an assumed 50 watts in the Thyratron-tube heater circuit was 110 watts. Volt-ampere demand is several times this value.

Whether fuses are satisfactory for arc-back protection depends primarily on the frequency of arc-back. For industrial use we do not believe that frequent arc-backs (one or two per month) are permissible in sets of the capacity considered here. If the rate is one in several years, as field experience is beginning to indicate in certain installations, fuses become practicable. Practice seems to indicate that a-c feeder breakers are usually required for transformer and arc-back protection and that double pole d-c breakers are required to remove short circuits. Anode breakers to provide the arc-back and short-circuit protection functions have proved quite satisfactory in certain installations.

Whether it is preferable to design the rectifier and switch gear as one unit or to combine separate units with the advantage of highly specialized design and manufacture in each would seem to depend primarily on the manufacturing organization.

The efficiency and loss figures were all based on 250-volt rectifiers. This omission has been corrected in the final paper.

Energy Flow in Electric Systems—The *Vi* Energy-Flow Postulate

Discussion and author's closure of paper 42-141 by Joseph Slepian, presented at the AIEE summer convention, Chicago, Ill., June 22–26, 1942, and published in AIEE TRANSACTIONS, 1942, December section, pages 835–41.

C. E. Bennett (Washington, D. C.): Ever since the time of Maxwell, students of electricity and magnetism have been intrigued by the problem of the mechanism of electric-power flow. Doctor Slepian's paper is a further contribution to the literature and presents interesting mathematical speculations without appearing to add anything tangible to our fund of knowledge regarding flow of electric energy or to impugn the validity of established engineering principles.

Doctor Slepian's paper is concerned, in general, with what he refers to as energy-flow "postulates." If the term applies to the mechanism of energy flow, one cannot quarrel with its usage. But if it refers to the flow itself, that is something that is not a "postulate." Whether it be a "phenomenon which can be actually physically observed" is a matter of indifference. Its effects, like the effects of heat, may be observed, and, as long as it may be measured accurately through its effects, the engineer will not worry about its observability. Whatever the nature of electric energy and the mechanism of its flow, the energy transfer itself is as much a reality as the metal conductor by which its flow from generator to load is implemented.

Throughout the paper, it is necessary to distinguish between energy flow as a reality and the mathematical assumptions and conclusions used in visualizing the mechanism of such flow. In his opening statement Doctor Slepian says:

> "Let V be the electric potential at any given point referred to some arbitrarily chosen point of zero potential."

Applying that definition to a three-phase circuit, if the neutral wire is assumed at zero potential, the result is the universally accepted one of energy flow in or about the three conductors. But if the point of zero potential be assumed on one of the three line conductors, then it appears from the application of these mathematical conventions that there is no energy flow in (or around, or adjacent to) that conductor (although it gets as hot as the others), and all of the energy flow is in or about the remaining conductors. Changing the hypothesis to assume another conductor at zero potential changes the apparent energy flow in that conductor to zero and seems to cause energy to flow in or about the conductor that previously carried nothing. Yet every engineer knows that grounding one conductor or another of an ungrounded three-phase system does not alter the energy flow. The writer of this discussion does not deny the occasional usefulness of such concepts, but he wishes to caution against confusing the consequences of mathematical assumptions with physical realities.

For practical reasons, engineers measure power flow by methods related to the totality VI product rather than by the summation of point functions discussed by Doctor Slepian. There does not appear to be anything in the paper to raise question as to the propriety of such methods, nor does the present commentator know of any meter or other device capable of integrating the point functions of Slepian and Poynting.

It should be noted that the voltages and currents associated with the conductors needed to interconnect generators and loads are determined by terminal conditions of the network and by the constants of the individual circuit elements. In consequence, the amounts of energy transmitted, lost, and stored or received, at any instant in association with any circuit element are fixed by the indicated parameters. Established engineering principles reveal the direction and magnitude of power flow through these elements but not the mechanism. The point-function "postulates" discussed by Doctor Slepian merely attempt to provide a mathematical picture of the mechanism of such flow. So far as concerns his use and control of electric energy, the engineer does not care whether the power flow takes place in the ether surrounding the conductors or in the conductor through the interatomic space by electron displacement, by a flow of electrons, by rotation of atomic dipoles, or by other means.

Against such a background some electrical engineers have read with surprise the eighth paragraph of the "Introduction" to Doctor Slepian's paper in which he says:

> ". . . . . the conditions just given are not sufficient for uniquely determining an energy flow . . . . which generation point is to feed which consumption point, and by what route, is completely undetermined so far as concerns any phenomenon which can be actually physically observed. Infinitely many postulates may be devised which will all be equally valid and equally well established by the conditions which have been described, and which are the only conditions which are available for defining an energy flow."

Doctor Slepian chooses not to elaborate on this point but allows it to appear as an incidental corollary, the relevancy of which is not disclosed in the paper. But Mr. Wagner, who presented Doctor Slepian's paper in the author's absence, and one of the engineers who took part in the discussion indicated that current interest in the mechanism of flow of electric energy has been aroused among engineers by its having been injected into certain regulatory Federal Power Commission cases,* in which decision turns upon the tracing of energy flows in a network. Doctor Slepian appeared as an expert witness in these cases and presented testimony for some 22 days regarding the flow of energy according to various energy-flow "postulates."

* It seems likely that the cases referred to (one of which is still pending before the commission) were Federal Power Commission dockets *IT*-5,563 and *IT*-5,565.

The full implications of the quoted statement become clearer from a consideration of Doctor Slepian's sworn testimony in the above cases. The following statements are noteworthy:

"There is no location in the geographic sense to the energy *per se*. You may calculate a certain energy by means of certain measurements made of objects having certain locations in space, but that does not mean necessarily that the energy resides there." (Slepian, FPC docket *IT*–5,563, transcript page 3,011, line 10.)

"The best location I can find for the energy, if I must have one, is in the mind of the calculator, strange as that may sound, if you must have a location." (Slepian, FPC docket *IT*–5,563, transcript page 3,012, line 10.)

The Federal Power Commission summarized Doctor Slepian's testimony regarding application of his views as to energy flow in a formal opinion (FPC docket *IT*-5,665, opinion 75, page 27), as follows:

"Such a method, *it was admitted* [italics by the discusser], would permit allocating to a generator in Hartford, Conn., the supply of a load in Shanghai, China, and to the Shanghai generator the supply of the load in Hartford, if such equality were observed, notwithstanding the fact that the Hartford generator appears to be electrically connected to the load in Hartford and the Shanghai generator to the load in Shanghai, while there appears to be no electrical connection between Shanghai and Hartford."

This is interesting as mathematical speculation, but, if considered as applicable to the physical world in which power companies operate, a theory of energy flow leading to such results would raise question as to a utility's legal right to collect money for electric energy used by its customers.

A certain difficulty of understanding Doctor Slepian's paper is due to the notation and may be clarified by an examination of section V, "Example of Failure of Simple *VI* Postulate." Discussing the case of a varying current flowing in a conductor having inductance but no resistance, he says:

"Hence if the simple *VI* postulate is valid, there should be appearing in the section an increasing amount of some form of energy, such as heat, for example. But no such energy appears there! The simple *VI* postulate fails!"

The explanation—his assumptions make it fail! By hypothesis, V is a scalar quantity determined by the location of point charges. It therefore excludes potential caused by induction. Doctor Slepian is simply pointing out that the Vi product excludes energy stored by induction. The "V" and "i" as used in his paper are not, therefore, to be confused with the corresponding Poynting vector quantities nor with the instantaneous values of potential difference and current which the engineer uses in the ordinary differential equations of electric circuits. Statements regarding the inexactness of the simple "*VI* postulate" should not, therefore, be interpreted as proving or disproving the exactness of the differential equations of electric circuits ordinarily used by electrical engineers.

S. W. Roland (Arlington, Va.) and **J. J. Jessel** (Falls Church, Va.): Doctor Slepian states that "the conditions which a valid postulated electric energy flow must satisfy . . . are insufficient for its unique determination. An analysis of this statement first requires that the term "postulated electric-energy flow" be defined.

The author obviously makes no distinction between measured and postulated electric-energy flows; that is, between energy flows that are continuously being measured and recorded at numerous points throughout an electric-power system and postulated flows which may be arbitrarily assumed for analytical purposes to exist at any point in space. He takes no cognizance of the fact that measured energy flows on the transmission and distribution circuits of a power system arise from consumer demands for electric power and that postulated flows, wholly independent of those demands, arise only when and if they are introduced by the analyst.

If one grants this distinction between measured and postulated electric-energy flows, it is evident that the question of uniquely determining energy flows on a power system concerns itself only with measured energy flows, particularly when such determinations are made in connection with legal proceedings. The term "energy flow" is a convenient expression used ordinarily to denote the transfer, transmission or conveyance of electric energy by electric currents.

The second question involved in the aforementioned statement by Doctor Slepian then becomes: "Can a unique determination be made of the measured electric-energy flows on a power system?" Before proceeding with an analysis of this question, it should be pointed out that it is common practice for electrical engineers to prepare diagrams showing both the magnitude and direction of power flows on the circuits of electric-power systems.

The 1942 edition of the "American Standard Definitions of Electrical Terms" includes the following definitions:

A-c transmission is the transfer of electric energy by alternating current from its source to one or more main receiving stations for subsequent distribution.

Radial feeder is a feeder supplying electric energy to a substation or feeding point which receives energy by no other means. (The normal flow of energy in such a feeder is in one direction only.)

Interconnection tie is a feeder interconnecting two electric supply systems. (The normal flow of energy in such a feeder may be in either direction.)

Power is the time rate of transferring or transforming energy.

Wattmeter is an instrument for measuring electric power.

The above definitions indicate clearly that the Sectional Committee on Definitions of Electrical Terms under the sponsorship of the AIEE, "representing some 33 organizations, including national engineering, scientific and professional societies, trade associations, government departments, and miscellaneous groups," recognizes that

1. Electric energy is transferred by electric currents from its source to points of consumption.

2. At any instant electric energy is transferred in a single ascertainable direction.

3. The time rate of such transfers can be measured by means of wattmeters.

Whether or not the afore-mentioned definitions are considered by the "trained mathematician" to be naïve, they do, nevertheless, in the words of their authors, "express for each term the meaning which is generally associated with it in electrical-engineering work in this country." It cannot be truthfully said that the authors of these definitions are "lay engineers."

The ascertainment of the magnitude and direction of energy flow on a circuit of a power system by means of appropriate instruments thus constitutes the unique determination of energy flow for that particular circuit. In many cases this information is sufficient to enable the engineer to make the unique determination of the energy flows from the various generating stations to the various loads on the system. In other cases, however, a knowledge of the magnitude and direction of energy flow in each circuit of a network may not suffice to enable the engineer to establish uniquely a continuity of individual flows from one circuit to another from a particular source to some specified point on the system. To illustrate, assume that each of several transmission circuits delivers energy from a separate source to one end of a substation bus; also, that several feeder circuits connected at the other end of the bus transmit energy to a number of distribution points. From which particular source or sources is each distribution center supplied? This question is a particularly sterile one to the engineer; yet it has been propounded to a number of engineers in legal proceedings involving the transmission of electric energy in interstate commerce. It appears that a solution to this question appropriate to jurisdictional problems involving the transmission of electric energy in interstate commerce will ultimately be forthcoming from administrative bodies and from courts. Thenceforth the engineer can guide himself accordingly in treating with problems of this type.

W. A. Lewis (Cornell University, Ithaca, N. Y.): I agree with Doctor Slepian in his derivation and his conclusions, as presented in this paper. However, from the standpoint of a reader whose background, in comparison with Doctor Slepian's, is somewhat more that of an engineer, and considerably less that of a physicist, I would express his conclusions in a different form. Doctor Slepian states that the *VI* postulate, as defined in the paper, is not generally valid when applied to any arbitrarily chosen volume in space, unless the additional term derived by him is included. I would prefer to say that the *VI* postulate, without the correction term, is valid when applied to a properly chosen volume, the properly chosen volume being one for which, at every point of the bounding surface, either the E_2 component of the electric intensity, as defined by Doctor Slepian, or the magnetic intensity H, is zero or perpendicular to the surface. With this restriction, the contribution to the energy-flow normal to the surface provided by the correction term of Doctor Slepian becomes zero, so that the integral obtained by the uncorrected *VI* postulate gives the entire energy flow through the bounding surface and therefore is completely valid as applied to this surface. This is true for the following reasons. If E_2 or H is zero, the correction term becomes zero. If either E_2 or H is perpendicular to the bounding surface, the energy flow, proportional to the vector product of E_2 and H, must be perpendicular to both E_2 and H and will therefore be tangent to the plane of the bounding surface. If the energy flow at the surface is zero, or if the direction of the energy flow is tangent to the bounding surface, the integral over the surface be-

comes zero, and the total correction term is therefore zero.

If this concept is applied to the examples cited by Doctor Slepian, it will be found that the volumes selected in the examples conform to the restrictions just given, whenever the unmodified *VI* postulate is valid, and do not conform whenever Doctor Slepian finds it to be invalid. The electrical engineer, in treating energy flow, generally obtains correct results because the bounding surface conforms to the restrictions imposed even though the engineer may not have been entirely conscious of that fact in planning the connections of his meters.

With these facts in mind we may say that Doctor Slepian has shown how the *VI* postulate may be corrected whenever the volume over which we wish to apply it does not conform to the stated restrictions.

The idea that the bounding surface involved in a problem must be specially chosen is not confined to the uncorrected *VI* postulate. For example, the Maxwell scalar potential given by equation (1) of the paper is obtained by integrating over all spaces, as stated by Doctor Slepian. As a matter of fact, the integral may be correctly obtained if it is extended only over all charges which are sufficiently close to the point in question or sufficiently large to provide a contribution to the potential integral. Any surface so selected that it includes all pertinent charges will enclose a suitable specially selected volume over which the integration may be carried out.

One additional caution must be exercised in the practical application of the *VI* postulate, in the unmodified form. Since V (of the *VI*) is actually V_m the Maxwell scalar potential, referred to a single common reference, care must be exercised to insure that the potential used, and impressed on the wattmeter potential coils, actually corresponds to V_m. As V_m at any point is obtained by taking the line integral of E_1 from the arbitrary potential reference point to the point in question, care must be used to select the reference point so that E_2 makes no contribution to the potential, or that it makes the same contribution to the potential at every point of the bounding surface where the current density is not zero, so that its effect will cancel when the complete integral is formed. The last follows because the total current flow normal to the surface of any closed volume is zero.

If the bounding surface is so selected that E_2 is zero or perpendicular to the surface at every point, the point of reference potential may be any point in the surface, and the paths of integration from the reference point to points where the several conductors cross the bounding surface may follow any path lying in the surface. Further care must be exercised, however, if some portion of the bounding surface has been selected perpendicular to H instead of E_2, since E_2 may then have a component tangent to the surface which might then contribute to the V_m integral if the path of integration passes through such a portion of the surface.

Myron Zucker (The Detroit Edison Company, Detroit, Mich.): This paper is important in its implications as to power-system interconnections, including questions of where the power generated in one station is consumed either through conductive transfers or by wireless methods.

It is unfortunate that the conventional analysis of this problem is treated so condescendingly in the paper. While it is true that the "*Vi*" postulate is tenable only under certain boundary conditions, these conditions are perfectly reasonable and are understood by the engineer in solving his problems. They are the same type of restrictions that must be set up in any scientific analysis and are similar to some of the assumptions that the author has had tacitly to make in his more general deductions.

The impression of the argument is also not improved by the neglect of resistance loss in the second example, when it provided the entire "sink" for energy in the case of discharging the sphere. Everybody knows that resistance loss accounts for an appreciable portion of the energy in the case of flow along wires, and it would seem as easy—and much more convincing—to admit that this occurs but to point out that it could not begin to satisfy the energy input under the conditions laid down by the author. To the layman (speaking from the mathematician's heights) who would have occasion to follow the analysis, the case would be much stronger for this modification.

At any rate, the paper shows definitely that there is more to the story of energy flow than simply adding together a few wattmeter readings.

Joseph Slepian: I wish to thank the three discussers from Washington for their remarks, which so well bring out and emphasize the major points of my paper: namely, that there are infinitely many, equally valid, energy-flow postulates and that the particular one frequently used by power engineers gives correct results as usually applied, for usual engineering purposes on power systems, but needs a correcting term to have the universal validity of the other widely used postulate, namely, the Poynting vector, and the many other valid postulates which may be and have been devised.

As Mr. Bennett brings out, electrical quantities are observed, defined, and even measured by the effects which are associated with them. In the case of electric-energy flow, these effects are the appearance of electric energy at generating points and the disappearance of electric energy at consumption points. All energy-flow postulates which are valid associate properly with and may be said to produce these observed effects. In this sense, all the various valid energy flows are equally well observed.

In his third paragraph, Mr. Bennett presents the interesting family of valid energy-flow postulates given by $P_s=(V+a)I$, where a is an arbitrary constant. The convention as to the zero of potential most generally accepted by power engineers is to take the earth as having zero potential. With this convention, the *VI* postulate makes the energy flow in any conductor proportional to its voltage relative to earth. If one conductor of a normally ungrounded three-phase system is grounded, the energy flow in that conductor according to the *VI* postulate is zero, and the reading of a wattmeter with potential coil connected to that line and ground is also zero. With a balanced load, the wattmeters in the other two lines show different readings, and one may even read in the opposite direction to the other. Nevertheless, the engineer will add up these readings, knowing that they will serve properly for the usual proper purposes for which valid energy-flow postulates are applied by power engineers.

Now Mr. Bennett points out that we may equally well take the neutral point of the system as the zero of potential. This will shift all potentials of the system by a constant a. All wattmeters will now give different readings and indicate different postulated energy flows in the individual lines. Nevertheless, as Mr. Bennett says, these different energy flows lead to the same results for usual proper purposes. This is because $P_s=(V+a)I$ is a valid energy-flow postulate. As Mr. Bennett says so well in his fourth paragraph, the engineer is indifferent as to the detailed individual energy flows asserted by the particular postulate he uses, so long as it meets his needs in "his use and control of electric energy."

I am very glad that Mr. Bennett referred to the Federal Power Commission hearings at which I served as an expert witness. The transcripts of these hearings make very interesting reading and may be obtained from Elecreporter, Inc., Washington, D. C. My own testimony in *IT*–5,563 runs from page 1,458 to 1,669 and from page 2,264 to 3,890. In *IT*–5,565 my testimony runs from page 2,102 to 2,242.

At the hearing (in *IT*–5,563), serving as expert witnesses and expressing opinions essentially similar to my own, in so far as they were permitted by the extraordinary rulings of the examiner, were R. S. Shankland, head of the physics department at the Case School of Applied Science; W. A. Lewis, head of the electrical engineering department at Cornell University; R. W. Sorensen, head of the electrical engineering department at California Institute of Technology, and past president of this Institute; V. Karapetoff, emeritus professor of electrical engineering at Cornell University. Also ready to testify, but not permitted by ruling of the examiner, was J. Stratton, professor of physics at Massachusetts Institute of Technology.

These hearings were carried on professedly following the procedure of a law court. The aim and purpose of the cross-examining attorneys was not the discovery and elucidation of the truth but quite definitely and solely the winning of their side of the case. Hence the questions put were designed as far as possible to elicit replies which might sound bizarre and strange to technically less expert people. Apparently the best of such replies which Mr. Bennett could find are given in his seventh paragraph. These quotations from my testimony are correct and are my well-considered opinion now. However, to understand them properly, they should be read in the context of the hearings at which they were given and particularly in relation to the questions to which they were answers. Space does not permit me to supply this context here, and the reader is referred to the available transcripts of the hearings.

The Federal Power Commission's opinion, given in the eighth paragraph of Mr. Bennett's discussion, shows a complete misunderstanding of my testimony at Hartford,

Conn., and misquotes it by the omission of a very important qualifying word.

Also, in this eighth paragraph, Mr. Bennett implies that the legal right of a utility to collect money for electric energy used by its customers somehow depended on the validity or invalidity of particular energy-flow postulates, presumably because some energy-flow postulate might show this energy as not deriving from some generator belonging to the utility. This is absurd. I say that my news dealer supplies me with my newspaper and pay him for it without thereby implying that he himself publishes it or creates it. In the same way I say that my light company supplies me with electric energy and pay my monthly bill, without implying or needing to be shown that the energy I consume does actually and recognizably come from some particular generator owned by my light company. That is a matter of indifference to me and, I think, has been made sufficiently clear in the last example of my paper.

In Mr. Bennett's last paragraph he implies that the potential V which I used is not the potential used by electrical engineers. This is not true. The potential V is the reading which a voltmeter would give if connected from a point in the line to the ground directly below. VI is the reading which an instantaneous wattmeter would give, if connected into and to the line at any point. The example given is one in which the assumption that electric energy flows only in conductors and is given by wattmeter readings there fails. The correcting term, which I have described in my paper and which gives a zero contribution in usual applications of electrical engineers, cannot be neglected in this example.

Roland and Jessel, who like Mr. Bennett are Federal Power Commission employees, try to distinguish between "postulated" and "measured" energy flows on a power system. By the "measured" energy flow in a line, I presume they mean the reading of a wattmeter connected to and into the line in question.

Now a wattmeter is an instrument with two pairs of terminals connecting respectively to two coils and so designed that its moving element is deflected by an amount which is a function of the average value of the product of the voltage applied to the one pair of terminals and the current flowing into the one and out the other of the other pair of terminals. If the first pair of terminals is connected, one to the line and the other to ground, and, if the second pair of terminals is connected in series relation into the line, then the wattmeter will read the average value of the product of the voltage of the line and the current in the line. About this there is no question. The wattmeter will read and thus measure the average value of VI for the line. But now when we assert that this average value of VI measured by the wattmeter is an electric-energy flow in the line, we make a postulate, which can only be justified, and that not uniquely, by showing that it does fulfill the only observable requirements, properties, or effects of a valid energy-flow postulate, namely that it does carry away from sources the proper amount of energy and bring to loads the proper amount of energy.

Now, subject to the correction developed in my paper, the VI postulate is a valid one, and wattmeters, properly connected to read VI, do measure energy flow according to the VI postulate. But Mr. Bennett has pointed out that wattmeters may also be connected to read $(V+a)I$, where $-a$ is the potential of the neutral of a three-phase system to ground. Asserting the existence of an energy flow in lines given by $(V+a)I$ is also a valid energy-flow postulate (again subject to the correction of my paper), and hence we may say that wattmeters so connected measure the energy flow according to the $(V+a)I$ energy-flow postulate.

In general, for any energy-flow postulate we may devise an instrument for measuring the quantities entering into the postulate, making the appropriate calculations with them, and exhibiting the result. Such an instrument may be said to measure the energy flow according to that energy-flow postulate. In general, for an arbitrary energy-flow postulate, the instrument will be much more complicated than the wattmeter. This, however, does not affect the principles involved in the question. The distinction which Roland and Jessel attempt to make between postulated and measured energy flows is without meaning.

In the last sentences of their discussion, Roland and Jessel reveal their understanding of the lack of physical meaning which is to be attached to questions to which different but equally valid energy-flow postulates give different answers. After describing a not particularly complicated system of several generators and several loads connected together, they ask, "From which particular source or sources is each distribution center supplied?" They anwer, "This question is a particularly sterile one to the engineer." Of course it is sterile. There is no one answer. Various energy-flow postulates, all equally valid, will give different mutually contradicting answers. They suggest that the answer will be forthcoming from administrative bodies and from courts. It is our duty as members of the engineering profession to ensure as far as possible that these bodies and courts will be technically well advised.

A New Multiple High-Speed Air Circuit Breaker for Mercury-Arc-Rectifier Anode Circuits and Its Relation to the Arc-Back Problem

Discussion and author's closure of paper 42-139 by J. W. Seaman and L. W. Morton, presented at the AIEE summer convention, Chicago, Ill., June 22–26, 1942, and published in AIEE TRANSACTIONS, 1942, November section, pages 788–96.

Otto Jensen (I-T-E Circuit Breaker Company, Philadelphia, Pa.): The authors have made a very thorough study of and have described in minute detail the conditions which exist in rectifier installations during backfires. Their conclusions regarding the advantages obtained by using anode circuit-breaker protection are clear and obvious. The initial effort to build anode circuit breakers for rectifier protection has developed to such an extent that there are now, installed and in successful service, 188 large rectifier units protected by I-T-E breakers; 148 more units are being installed, and 175 additional breakers are in production. We then have a total of 511 units of anode circuit breakers protecting rectifiers made by all of the three manufacturers. This means that there are 1,128 poles in operation, 888 poles being installed, and 1,050 poles now in production, a total of 3,066 poles. With these figures in mind we must realize that the anode-breaker protection scheme is not new.

We note in Figure 4 of the paper that the customary high-voltage oil circuit breakers for the protection of the rectifier transformer are still advocated, and, from paragraph 3, in the conclusion, that the maintenance of the a-c power circuit breaker is reduced, because the circuit breaker is no longer required to do any work.

Our opinion may be a little biased, but we do not see any reason for installing a piece of electric equipment which has no duty to perform, particularly in times like these when our manufacturing facilities could certainly be better utilized if they were devoted to the manufacture of necessary equipment. We can however, understand the fact that, if an oil circuit breaker has no duty to perform, it is not a too undesirable piece of equipment.

We note from Figure 10 of the paper that the initial rate of rise of anode circuit 1 is approximately 6,300,000 amperes per second, and the initial rate of rise for anode 5 is 9,000,000 amperes per second. We assume that the steeper rate of rise for anode 5 is due to the d-c saturation of the transformer core caused by backfiring current of anode 1.

We do not understand the quarter-cycle delay in the reversal of the cathode current. If this is a typical condition, it further emphasizes the undesirability of cathode switching, because there is evidently a quarter-cycle delay before the cathode breaker would "know" that a backfire had occurred, and consequently the opening of the cathode breaker has been unnecessarily delayed.

Evidently, any number of backfires could have occurred up to the time that the medium-speed cathode breaker opened the circuit, and evidently the successive backfires are increasingly severe. We therefore, raise the question: Would it not be highly desirable to use a high-speed rather than a medium-speed cathode breaker in order to cut down the time interval in which sympathetic backfires could occur?

We notice the statement that the artificial backfires are more severe than the natural backfires because of the limiting effect of the arc drop in the rectifier element. This statement does not seem to be substantiated by the oscillographic record in Figure 10 of the paper, because the natural backfire in anode 5 is more severe than the artificial backfire in anode 1 both as to the amount of current and the elapsed time.

Great stress has been laid upon the design feature of the circuit breaker which prevents it from opening on any amount of forward current. We see no particular advantage in

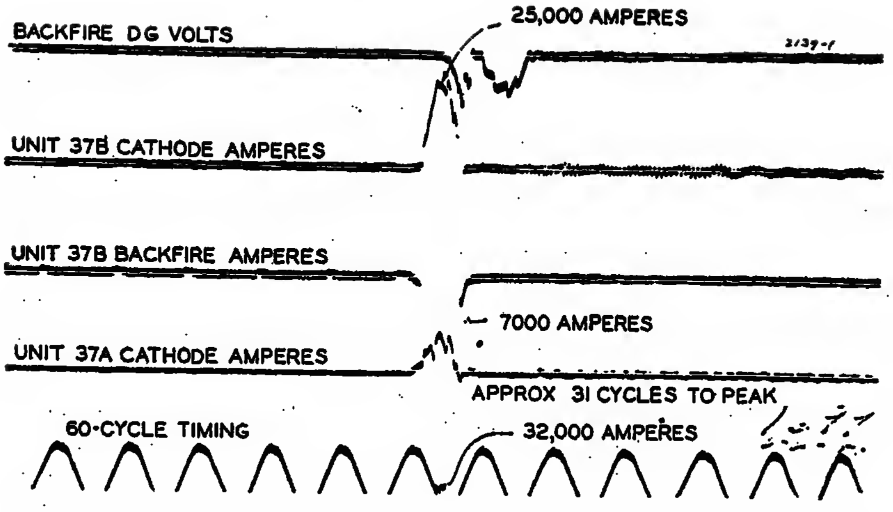

Figure 1. Backfire on rectifier 37-*B*

this. We believe a safer installation would have resulted had the breaker been deliberately designed so that it would not open up under the amount of forward current supplied by the anodes in the companion tank during backfire but would open up under forward anode current produced by the healthy anodes in case of a direct short circuit of one rectifier.

I-T-E oscillograph 7699 might better illustrate this point. A backfire was made on rectifier 37-*B*, and rectifier 37-*A* is the only other source which could feed the fault. Under this condition, the forward current which can be furnished by any other rectifier on the bus becomes the greatest obtainable from any one rectifier anode. Rectifier 37-*A* anode breaker did not trip, and this rectifier, therefore, continued to feed the d-c bus. If a short circuit had been applied to the bus, we know from a-c tests of our breaker that it would have tripped if any of the anodes had contributed more than 30,000 amperes to the fault, thereby furnishing high-speed short-circuit protection.

We cannot agree with the statement on the basic requirements that the breaker would be fully acceptable if it limited the fault current in one half-cycle. We feel that a quarter-cycle circuit breaker is more desirable than a half-cycle circuit breaker and that a tenth-cycle circuit breaker is certainly more desirable than a quarter-cycle breaker. Our oscillogram 11, published in AIEE paper 42-38 entitled "A Fast Circuit Breaker,"[1] shows the comparison between a half-cycle breaker and a quarter-cycle breaker.

Inasmuch as all the rectifier and circuit-breaker manufacturers now agree that the anode-breaker protection scheme is the most desirable, and since this scheme is based on ultrahigh speed operation, why isn't it good engineering to use the fastest circuit breaker known in the art?

H. Winograd (Allis-Chalmers Manufacturing Company, Milwaukee, Wis.): The authors have presented a lucid exposition on the arc-back problem in rectifiers and the requirements for protection. Additional comments on this subject will be made here.

The arc-back tendency of a rectifier is related to the current and voltage rating and circuit constants by two basic factors:

1. The residual ionization in the vicinity of the anode at the conclusion of its firing period.

2. The magnitude of the negative voltage appearing between the anode and cathode at that instant. This may be termed the recovery voltage (see Figure 2 of this discussion).

At the completion of the firing period, the residual ions are drawn toward the anode surface by the negative voltage gradient, causing the flow of a small "inverse" current. The magnitude of this current depends on the density of ionization and the value of the recovery voltage. If the inverse current density at any point on the anode surface becomes sufficiently high, a cathode spot and arc discharge may be initiated. This is one of the generally accepted theories on the causes of arc-backs. Arc-backs resulting from this cause would be most likely to occur at the end of the firing period of the anode. Investigation made in one rectifier installation indicated that most arc-backs do occur at that part of the cycle. The random nature of such arc-backs is probably related to the distribution of the forward current at the surface of the anode, which would affect the density of residual ionization.

It is obvious that the higher the load current and operating voltage, the greater would be the inverse current of a rectifier and its tendency to arc-backs.

This might also offer an explanation of the effect of circuit constants such as the transformer and a-c system reactances on the tendency to arc-backs, mentioned by the authors. The commutating reactance determines the length of the commutating period for the anodes. The higher the commutating reactance, the larger is the commutating period, and the more gradual is the decay of the anode current. This provides more time for deionization, and the density of residual ionization is thereby reduced. On the other hand, the longer commutation period results in a higher recovery voltage at the end of the firing period. The two effects are opposite in their relation to arc-backs. The net effect would probably depend on the speed of deionization while the current is declining, that is, on the design of the rectifier.

It is well known that, the more the firing of the anodes is retarded, by grid or firing control in order to reduce the d-c voltage of a rectifier, the greater is the tendency to arc-backs. This also can be explained on the basis of residual ionization and recovery voltage.

The greater the retardation of the firing period, the higher is the recovery voltage, and the shorter the commutating period, which would increase the residual ionization. The inverse current would therefore be increased by both factors.

Another point of interest in connection with arc-backs, not mentioned by the authors, is the effect of the point in the cycle at which an arc-back occurs on the rate of rise of the current to the faulty anode and the value of current reached in one-half cycle. The highest value is obtained if the arc-back starts at the completion of the forward firing period. It becomes progressively smaller as the arc-back point is moved back along the reverse voltage wave. Beyond a certain point, depending on the circuit constants, the current would drop to zero, and the anode could fire in the forward direction. Arc-backs occurring during that part of the cycle might extinguish themselves without tripping the breaker. These are called "silent" arc-backs.

It would be of interest to add a historical note relating to the introduction and development of the high-speed anode breakers. Credit for this development in the protection of rectifiers is due to D. I. Bohn, electrical engineer of the Aluminum Company of America. In 1938, the first rectifiers used in this country for production of aluminum were put in operation at the Alcoa and Massena plants of the Aluminum Company. These had the conventional protective system—a-c breakers on the primary side of the transformers and high-speed cathode breakers.

In 1939, when the Aluminum Company decided to order rectifier equipment for another pot line at Alcoa, Mr. Bohn (being unfettered by tradition) proposed using anode breakers, in order to eliminate oil circuit breakers for the individual rectifier units. As engineer representing the manufacturer of the rectifiers, the writer readily agreed, since the advantages of the protection of the rectifier equipment were obvious.

As there was no high-speed breaker of this type available, Mr. Bohn proceeded to develop one himself. The writer had the pleasure of assisting him on the tests of this breaker. The I-T-E Circuit Breaker Company co-operated in this development. The rectifier equipment with the anode breakers was placed in operation in the spring of 1940.

This installation included other features relating to the design of transformers, protection, switching, layout, and cooling, which set the pattern for many subsequent rectifier installations in the electrochemical industries, as described in some of the other papers presented at the summer convention of the AIEE.

This is a tribute to the good judgment and foresight of an engineer in an important industry, and it again points to the benefits derived from close co-operation and exchange of ideas between engineers of operating and manufacturing companies.

O. K. Marti (Allis-Chalmers Manufacturing Company, Milwaukee, Wis.): The authors of this paper deserve a great deal of credit for having submitted an excellent outline and valuable data illustrating the arc-back phenomenon, as well as interesting design material on a new anode breaker. During the last few years considerable attention has been given to improving means for anode switching in order to minimize the effect of backfires. During the last winter convention of the AIEE a paper was presented by D. I. Bohn and Otto Jensen referring to the development of "A Fast Circuit Breaker," which has been used successfully in connection with many rectifiers.

It is felt that the following notes concerning the earlier pioneering history of anode-breaker development may also be of interest to many engineers.

Figure 5. 850-kw 625-volt automatic rectifier unit

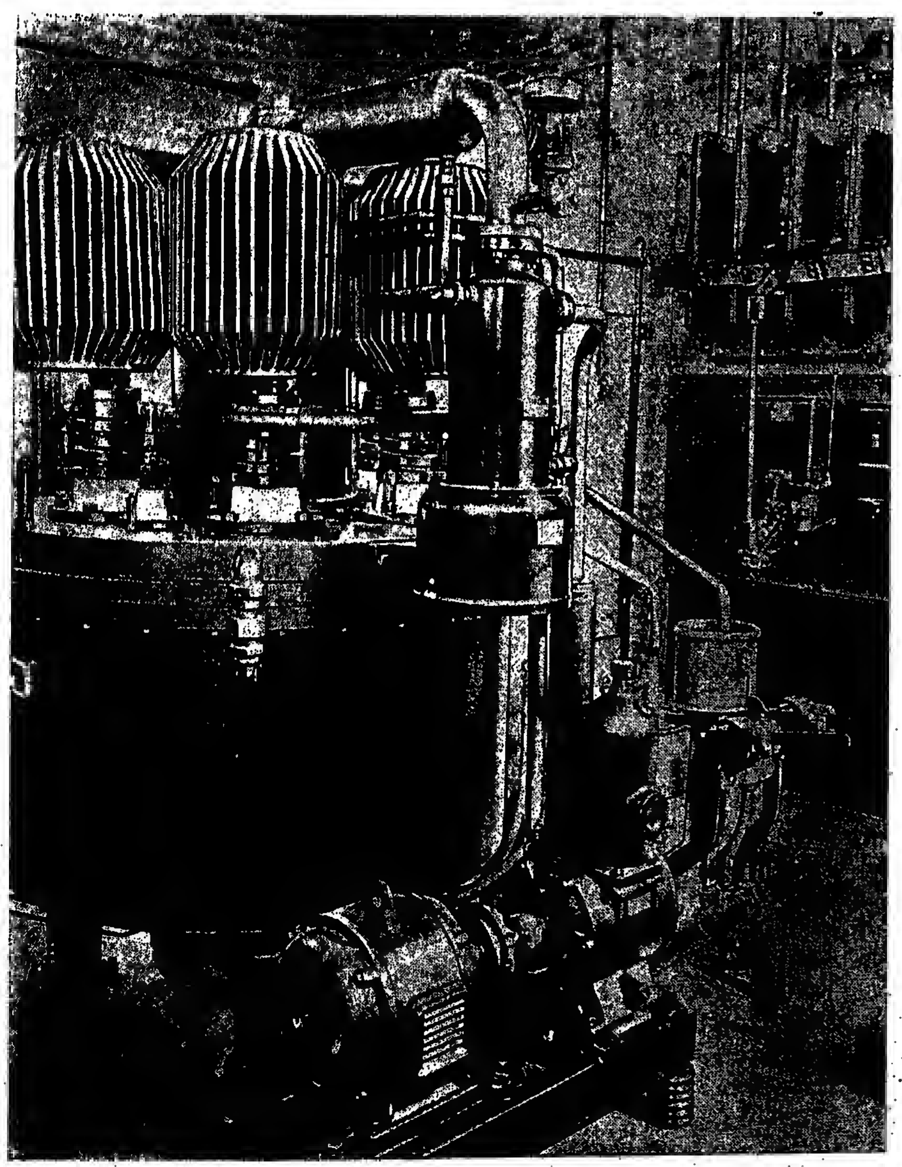

Figure 6 (below). Grid-controlled mercury-arc rectifiers rated 2,750 kw, 600 volts, direct current each, in electrolytic metal reduction plant

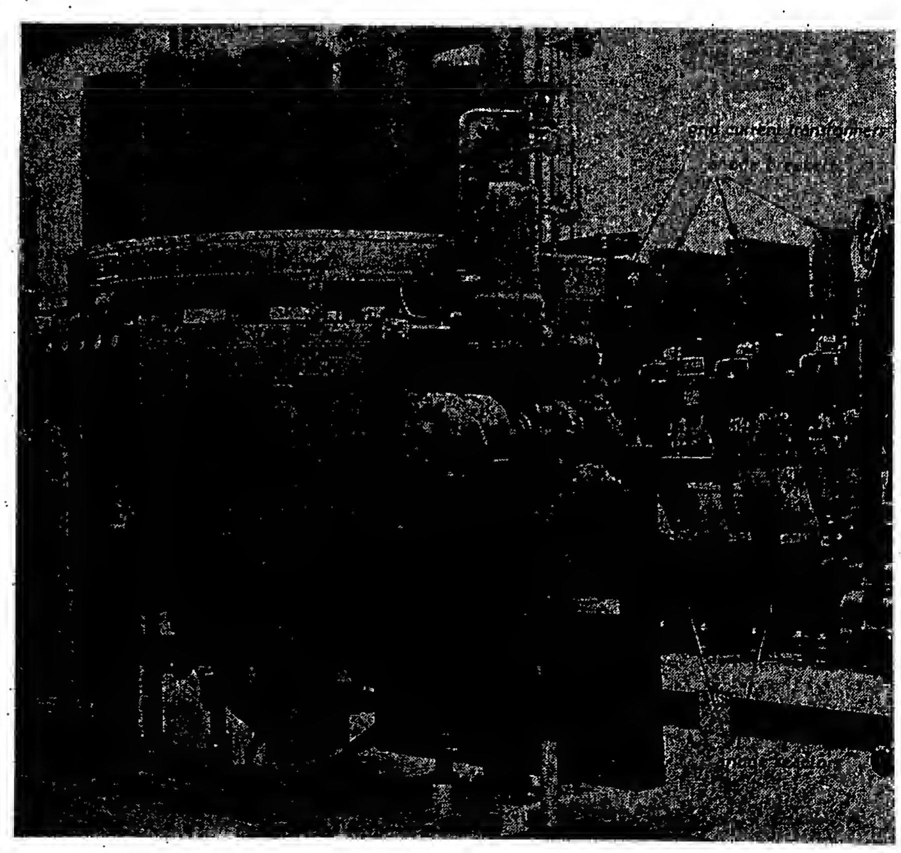
Anode breakers and anode reactors in background



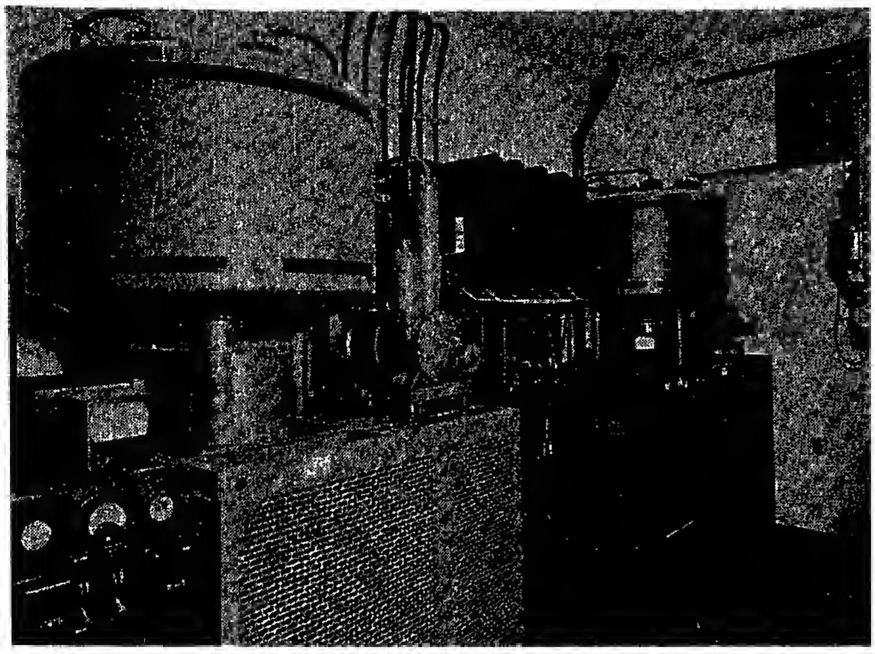


Figure 7. Two direct air-cooled multianode rectifiers, each rated 300 kw, 600 volts direct current with common six-pole anode breaker

In 1931, we were asked to prepare data in connection with the modernization of an electric-railway system, using mercury-arc rectifiers of medium capacity. During the early stage of this investigation it was found that the cost of the a-c switching equipment was quite out of line compared to the cost of the total equipment, because of the high voltage of the power circuit from which the rectifiers would have to be fed. The study showed that a very economical and satisfactory installation fully protecting the rectifiers could be obtained by using six single-pole d-c breakers for the anode leads and replacing the relatively costly a-c line breakers.

To determine the feasibility of such a scheme, the necessary equipment was set up in the factory in order to test a six-pole breaker made up from standard d-c breaker elements. The testing equipment consisted of a 3,700-kva rectifier transformer with interphase transformers, a six-anode rectifier, a short-circuiting device, and a load rheostat, and so forth (see Figure 3). During these tests the six-pole breaker was first closed and the rectifier brought up to a load of about 350 kw on a water rheostat. Then several short circuits were applied, first between one anode and cathode and second between cathode and the transformer neutral. In all of these tests the breaker interrupted in less than six cycles (see Figure 4), and the contacts showed practically no signs of pitting or burning so that the breakers could be shipped without changing the contacts. One of the installations equipped with such anode breakers and without an a-c line breaker is shown in Figure 5. Excellent service was obtained, and, considering that this breaker was not designed for such an application, the results were very encouraging.

It was not until 1939 that an occasion arose to use this scheme in a large plant. However, for this application, a specially designed anode breaker was employed.

Figure 6 shows the first installation of these anode breakers, described by Bohn and Jensen, in a plant with a number of rectifiers connected in parallel. The breakers in this installation are called on to interrupt not only the regular backfire current, but also the current component fed from the rectifiers connected in parallel. In the above case the installation consisted of 12 4,500-ampere units.

Figure 7 shows one of two recently installed substations of a 600-kw air-cooled rectifier unit which has as its only protection a six-pole anode breaker. This application of anode switching has also given excellent service for over a year.

J. W. Seaman and L. W. Morton: The authors are pleased to note the unanimity of agreement, that advantages obtained by using high-speed anode switching are clear and obvious. It was especially the purpose of part I, "Analysis of the Arc-Back Problem" to make a record of the reasons for these advantages. As Mr. Jensen states, high-speed anode-breaker protection is not new, but it is, however, the latest method for protection from arc-back, and, in the authors' opinion, superior to several other methods.

Use of anode switching to protect from arc-back is by no means a substitute for adequate a-c power-circuit-breaker protection of the rectifier transformer from internal faults or short circuits. Incidentally, the authors did not specify oil circuit breakers, preferring to use the broader description, "a-c power circuit breaker." Wide engineering acceptance is given to the practice of protecting any transformer of substantial rating (and many rectifier transformers are as large as 7,000 kva), by means of its own a-c power circuit breaker. Such a power breaker does have a duty to perform, and that is to protect its associated transformer from extensive damage caused by internal faults and to assure continuity of production by clearing such faults from the system instantly. It is quite conceivable that with less than adequate a-c power-circuit-breaker protection faults other than arc-back might produce damage to apparatus and loss of war production, far out of proportion to any that could be made by omitting a-c switchgear.

It is likely that transformer saturation did contribute to the higher rate of rise for the anode involved in the natural arc-back in Figure 10 of the paper. In addition, the inductance of the short-circuiting cable in circuit 1 may have had some effect. A further contributing cause may have been the exact time that the short-circuiting breaker contacts happened to close. It is believed that the contacts closed slightly after the end of conduction in circuit 1, during the test illustrated by Figure 10. A slight difference in time, even though not detectable on the oscillogram, may reduce the rate of rise and the ultimate short-circuit current. Other oscillograms in the same series of tests show higher current in circuit 1 than in other anodes involved in natural arc-back, and it is suspected that the main reason was that the short-circuit contacts closed earlier.

The statement that artificial arc-backs are more severe than natural ones and therefore err on the safe side, should be qualified by adding that the reactance and resistance in the short-circuiting cables must be kept to a minimum, and the comparison should be made using tests when the short-circuiting contacts closed before the end of forward conduction.

The authors have noted the quarter-cycle delay in reversal in cathode current in tests illustrated by Figure 10 and in other tests also. No convincing explanation has been prepared. The delays were probably caused by some obscure inductive effect.

It is true that any number of arc-backs, even up to all six anodes in the rectifier, could have occurred before the cathode breaker opened. It is also true that a high-speed cathode breaker rather than medium-speed breaker offers the maximum in protection from sympathetic arc-backs. However, actual experience proves that this is unnecessary. Seldom, with high-speed anode switching, do anodes in the other wye become involved in the arc-back. Furthermore, as is shown in Figure 10, the maximum reverse current from other rectifiers on the same bus is periodically reduced by the opening of the anode-breaker switches whose anodes are in arc-back. Finally, this limited reverse current is usually supplied and shared by all the other rectifiers so that the duty imposed on any one rectifier is far lower than its momentary overload capacity.

The feature of this breaker which prevents it from opening on any amount of forward current makes the breaker applicable to a wider variety of installations. Referring to Figure 2 of the paper, it can be seen that forward current contributed by anodes 4 and 6, reached values dangerously near such a low forward tripping current as 31,000 amperes. There will be many applications when it is desirable to trip only the one anode which arcs back and not the cathode breaker at all. Such provision preserves continuity of service by allowing the rectifier to remain in service on the remaining healthy anodes. This breaker also, as was pointed out, is designed to permit reclosing any open pole or poles, without interruption of service. This consideration alone justifies the "no trip on forward current" feature. Protection from short circuit on the rectifier is afforded by a discriminating overcurrent tripping mechanism in the medium-speed cathode breaker.

The authors agree that the faster the interruption, the better the breaker for arc-back protection up to the point where voltage surges are created. It has been observed that faster arc extinction than that employed in this breaker does give rise to such surges. Attention is called to the fact that no surges were observed during tests on the breaker described. Any improvement in speed of mechanically starting contact separation is safe and desirable, but this is not true of arc extinction.

Dr. Marti's discussion presents inter-

esting and valuable historical notes bearing on the subject. It furnishes a good example of the efforts engineers have made to solve satisfactorily the arc-back problem in the past and shows an appreciation of the advantages of anode breakers. Many such instances could be related by the various groups who have been working with power rectifiers.

Mr. Winograd's comments constitute valuable additional data regarding mechanism of arc-back to that presented in the paper. The point raised about the effect of the time in the cycle at which arc-back occurs, influencing the rate of rise and ultimate value of arc-back current, is particularly timely. This effect was noted in connection with the whole series of tests conducted on the anode breaker and is of sufficient importance to emphasize.

Mr. Winograd is another who suggests that the anode breaker is a substitute for adequate a-c switchgear. Such a tendency seems dangerous to the authors, as it overlooks other sound and sufficient reasons for not omitting rectifier-transformer protection. The many advantages of high-speed anode switching for arc-back protection alone, set forth in the paper, surely in themselves justify the use of the breaker, and it is not necessary to resort to doubtful omissions to balance the scales.

Ignitor Excitation Circuits and Misfire Indication Circuits

Discussion and author's closure of paper 42-105 by A. H. Mittag and A. Schmidt, Jr., presented at the AIEE summer convention, Chicago, Ill., June 22–26, 1942, and published in AIEE TRANSACTIONS, 1942, August section, pages 574–7.

O. K. Marti (Allis-Chalmers Manufacturing Company, Wilwaukee, Wis.): This paper illustrates in a very interesting way what can be accomplished by approaching a problem step by step in a systematic procedure. It is therefore of value not only in its particular field but in a general way as well.

In a paper, "Excitron Mercury-Arc Rectifiers," presented at the winter convention of the AIEE in 1940,[1] I called attention to some of the shortcomings of the intermittent ignitor excitation scheme and discussed the continuous ignition-excitation system used in connection with the Allis-Chalmers single-anode Excitron rectifier. This paper was not very kindly received, especially the remarks regarding misfiring.

The paper under discussion, now, however gives an outline of some interesting work directed mainly toward overcoming the very disturbing phenomena to which I drew attention in 1940 and to developing means for recording these distrubances. Since my paper was presented, we have seen the introduction of a holding and relieving anode in addition to the ignitor in the ignitron rectifier, as well as a rather complicated circuit, in order to obtain faultless operation with reduced power consumption. This is the case in spite of the fact that the authors have greatly contributed to the simplification and successful operation of the ignitor excitation system. On the other hand, in connection with the Excitron rectifier using continuous ignition excitation, it was possible during the last two years to simplify the circuit somewhat, as well as the rectifier tank, since for most services satisfactory operation is being obtained with one auxiliary anode used as an ignition and excitation electrode. The circuit of this new scheme is simpler than the one presented two years ago, and the phenomenon of misfiring does not have to be contended with. In this system, if the excitation should fail, it will be automatically restored. Since the auxiliary anode is removed from the mercury, any change in mercury level or metallization of the ignition-excitation anode does not have any detrimental effect in connection with the function of the ignition-excitation system.

From the paper of J. H. Cox and G. F. Jones, "Ignitron Rectifiers in Industry,"[2] it can be seen that in connection with the ignitor rectifier a grid is located next to the anode for shielding. Such a grid is also used with the Excitron rectifier for phase voltage control, employing the well-known method commonly used in connection with multiple-anode tank rectifiers. Therefore, in order to regulate the output voltage, the ignition-excitation does not have to be disturbed as in the ignitron rectifier, which may lead to further misfiring, especially if the firing is delayed beyond the first half of the positive cycle.

2. IGNITRON RECTIFIERS IN INDUSTRY, J. H. Cox and G. F. Jones. AIEE TRANSACTIONS, volume 61, 1942, October section, pages 713–18.

J. H. Cox (Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa.): The authors indicate that the ignition impulse desired for ignitron excitation should be as steep as possible. This is true only within limits and may hold for magnetic impulse circuits since it is impossible to attain really steep impulses with such circuits. It may be undesirable to use impulses as steep as can be produced with thyratron-capacitor circuits. There is considerable evidence which indicates that, if the impulses are too steep, more instantaneous energy is applied to the ignitor than necessary, and difficulties may be encountered. On the other hand, if an ignitor becomes contaminated with surface impurities, it may be desirable to use a more sloping impulse which will apply more heating energy to the ignitor and increase its temperature. Therefore, the most desirable impulse shape is one which provides a balance between a slope which applies the correct amount of average energy and, a steepness which avoids variability in the time of ignition and a resulting unbalance between anode currents. We have found that such impulses are produced by those saturating reactor circuits which have special iron, such as Hypernik or Hypersil, in the saturating reactor and no additional reactance to further increase the length of the wave front.

The authors mention a relieving anode to take the arc current which follows the creation of the cathode spot and thus relieve the ignitor of this current. Actually, the ignitor will be relieved in any event, because after the appearance of the cathode spot any follow current will pass between the ignitor holder or rod, and the mercury and the ignitor will be shunted. Therefore, it is only necessary that the holder have sufficient area to conduct for follow current provided by the excitation circuit. With the practical construction used in large pumped-type ignitrons, this holder area is ample for any circuit that has been used. In the smaller sealed-off ignitron construction the holder area and the lead-in conductor are both much smaller and would be overloaded with the more powerful circuits. However, the smaller tubes require less ignition power, and the lower energy circuits are entirely adequate.

The autotransformer, which the authors show for the purpose of directing the successive impulses of opposite polarity to opposing ignitors and thus enable one circuit to service two ignitrons, performs the same function as the Rectox arrangement shown in Figure 4 of the paper "Excitation Circuits for Ignitron Rectifiers" presented at the summer convention of 1941.[1] The transformer connection imposes full voltage across the series Rectox, increasing its size, whereas a parallel Rectox imposes only its forward voltage drop across the series Rectox. There is probably little to choose between the two methods.

I question the statement that misleading results are obtained from the determination of circuit output characteristics by replacing the ignitor with a resistance load. The curve obtained by a variable resistance load should give an accurate determination of the maximum capacity. It frequently occurs that a circuit will operate stably with resistance load and have unstable characteristics when loaded with ignitors. This characteristic, of course, will show up in tests which include ignitors, but a circuit which is stable with ignitors can be calibrated by the substitution of a variable resistor. Also, in our recent production, excitation equipment adjusted at the factory by the use of a resistor required no further adjustments in the field.

In connection with misfires, there is some question whether the complication imposed by misfire indicators is justified. There is a great deal of operating experience which indicates that no serious consequences result from a failure of an anode to pick up, either intermittently or continuously, for either a variable type of load such as is encountered in railways or with steady loads as encountered in electrochemical service. In the design of anode balance coils it is entirely feasible to provide open-end impedance which avoids the overloading of an anode when the anode with which it is paired goes out of service. Actually, if an anode goes out of service it is indicated by several things, such as a lower voltage, lower current when paralleled with other units, noise in the anode balance coil when these are used, or fluctuating ammeter reading if the ammeter happens to be a fairly sensitive type. As the authors have indicated, it is a relatively simple matter to find the particular anode which is missing when it is known that a misfire exists in an assembly. Of course, in an automatic station some type of misfire indicator might

be desirable to give indication at some distant point, and the authors have listed various satisfactory circuits that may be used.

REFERENCE

1. EXCITATION CIRCUITS FOR IGNITRON RECTIFIERS, H. C. Myers and J. H. Cox. AIEE TRANSACTIONS, volume 60, 1941, October section, pages 943–8.

A. H. Mittag and **A. Schmidt, Jr.**: The relieving anode performs the following functions:

1. Reduction of duty on dry-plate rectifier in series with ignitor.
2. Reduction of duty on ignitor in circuits with high total energy.
3. Stabilization of low energy circuits where aging of dry plate rectifier may change the circuit resistance and resulting performance.

It is our experience that a correct picture of maximum energy for ignitor firing is best obtained by use of the circuit shown in Figure 6 of the paper. In particular, the increase in firing energy in a "twin" circuit, shown in Figure 7, is not evident with a resistance-testing circuit. If the excitation circuit has considerable excess capacity, a testing method with a large margin of error may indicate acceptable operation.

The need for misfire indication equipment is not always present. Such equipment would seem desirable in certain applications, particularly in automatic stations and in certain industrial applications, particularly nonattended stations.

A 600-Volt Enclosed Limiter for Network Use

Discussion of paper 42-99 by P. O. Langguth, H. L. Rawlins, and J. M. Wallace, presented at the AIEE summer convention, Chicago, Ill., June 22–26, 1942, July section, pages 536–8.

Charles P. West (Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa.): Limiters comprise an essential feature of secondary distribution and industrial-network systems and provide the best-known means of selecting faults in the loop cables. Their time characteristics and fusing points, when properly co-ordinated with the cables, give isolation of a faulty conductor, without power interruption or disconnection of any sound part of the system. The authors have clearly covered the design and development of the extension of limiters from 250-volt to 600-volt service. Their places in the circuits, with the breakers and other devices, have been shown on the diagram (Figure 10 of the paper). Their physical association with other equipment should also be carefully considered, to obtain the maximum advantages of the device. When the limiters have cleared the defective cable, a new conductor must be installed. A well-planned system includes structures designed to safely allow replacement of this conductor with the remainder of the apparatus in operation.

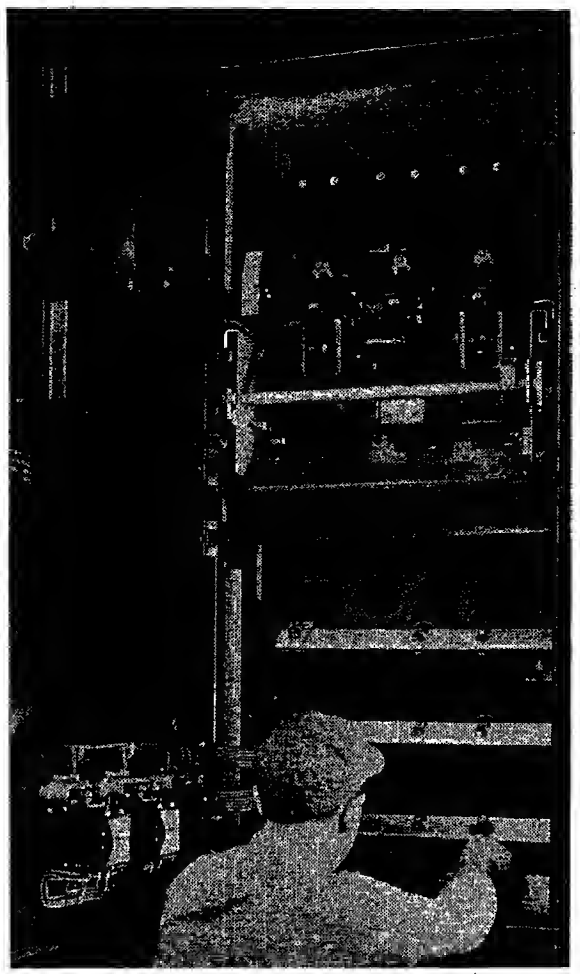

Figure 1

Figure 1 of this discussion shows part of the front of a low-voltage metal-enclosed switchgear structure designed for application to an industrial network, sections of which provide compartments for the loop-isolating switches (nonautomatic air breakers, in this case) and limiters. The limiters are normally bolted to the three-phase busses carried across the unit, and a workman is shown unbolting a limiter from the lower-phase bar. Phase isolation is provided so that the limiter can be removed safely while alive, if necessary.

Figure 2 of this discussion shows the rear of this compartment, with the three conductors of one loop cable in place and the limiters for the second cable. The lower right limiter has the insulating cover removed. The workman is holding a limiter and cover showing how they fit together. When such a structure is in operation, a faulty limiter and cable can be disconnected from the bus and drawn into the rear compartment. It will then reach into the clear space behind the gear, and the cable can be pulled out of the conduit. The new cable is pulled in and its limiter attached and connected to the bus in a similar manner.

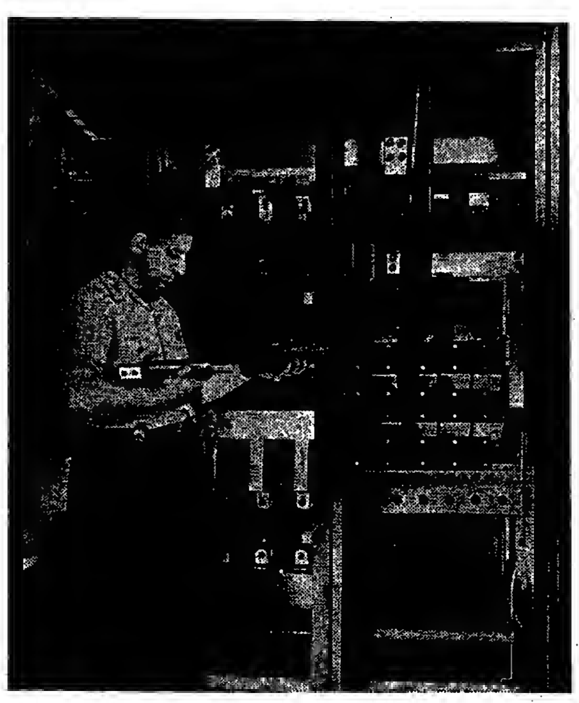

Figure 2

Thus, proper housing and mounting of limiters provides means for replacing faulted cables in the shortest time with no loss of power to the remaining parts of the system. The use of compartments in the switchgear provides isolation for the various devices, gives a co-ordinated design, permits shipment of structures completely assembled, and makes possible all the advantages available in standardized groupings.

Electric Equipment for Large Electrochemical Installations

Discussion of paper 42-138 by T. R. Rhea and H. H. Zielinski, presented at the AIEE summer convention, Chicago, Ill., June 22–26, 1942, and at the AIEE Pacific Coast convention, Vancouver, B. C., Canada, September 9–11, 1942, and published in AIEE TRANSACTIONS, 1942, October section, pages 733–41. The following discussion was presented at the 1942 summer convention.

W. E. Gutzwiller (Allis-Chalmers Manufacturing Company, Milwaukee, Wis.): This paper is a very timely one and covers thoroughly all phases of rectifier application to modern electrolytic plants.

It is apparent from the statistical figures in the paper that the national defense program and the war have been responsible for an unprecedented demand for power rectifiers in the electrochemical industry. This demand raised, in the short span of approximately three years, the total capacity of rectifiers installed and on order in the United States from approximately 900,000 to nearly 3,000,000 kw.

Such an enormous increase in production, on short notice and of a rather intricate piece of equipment, could be met only because some farsighted electrochemical companies had early recognized the advantages of rectifiers for electrolytic processes and had made some trial installations. The manufacturers of rectifiers were thus able to gain valuable experience and, when the defense program got under way, were well acquainted with the peculiar requirements of electrolytic processes which the authors justly state are usually of a secret nature.

The first rectifier application to an electrolytic zinc refinery was made in 1929 in a Canadian plant. Rectifiers were used for the first time in an American chlorine plant in 1934, where, since then, they have had a revolutionizing effect on cell circuit layouts, having been responsible for an increase in operating voltage from 250 to 600 and 750 volts. The year 1938 saw the first use of rectifiers in an American aluminum plant. Step by step the rectifier conquered all the electrolytic processes where electric power is an important item in the production cost. Each of these processes in the order mentioned presented new problems of rectifier application.

Because of the large amount of power required for operation of modern aluminum-reduction circuits (45,000 to 55,000 amperes at 650 volts) high-speed grid blocking and high-power high-speed rectifier switchgear had to be developed to protect the equipment against destructive fault currents.

It is only appropriate to give the Aluminum Company of America credit for having not only encouraged the manufacturers but actually initiated and taken an active part in the development of a high-speed anode breaker which is now being adopted generally by all rectifier manufacturers and operators for high-power rectifier installations.

It is interesting to note that all rectifier pioneering in the electrolytic field, as mentioned before, was carried out with the continuously excited multianode rectifier, which is still being purchased by many users on the strength of its good operating records. However, the single-anode, intermittently excited ignitron type, as well as the continuously excited Excitron type, are being chosen for many high-power installations of medium d-c voltages because of their higher efficiency and greater operating flexibility.

The authors state that continuous use of grid control should be limited to four or five per cent because of the low power factor and greater tendency to arc back. The main reason for the increase in arc-backs, which should be of interest to operators, is as follows: The more grid or igniter control is applied, the more is the firing or "pickup" point of an anode delayed; likewise, is the drop-off point at the end of the firing period delayed and shifted toward the negative half of the voltage wave. The result is that with increased firing delay the voltage between anode and cathode at the end of the firing period rises faster to a negative value, thus reducing the deionizing time of the electronic valve and increasing the reverse current to the anode caused by the residual ionization. Excess reverse current at the end of the firing period causes electron emission at the anode, a common cause for arc-backs. The effect of grid control on arc-backs at reduced load is less pronounced because of the reduced ionization prevailing under this condition. Grid control may thus be used for starting duty on electrolytic cells.

Referring to the matter of high-speed d-c switchgear, in chlorine plants, where, as a rule, one or two rectifiers are paralleled with a total bus load of 7,000 to 8,000 amperes, semihigh-speed cathode breakers with grid or igniter blocking have been found satisfactory. Likewise, installations with anode breakers and a maximum of 8,000 amperes per bus, are now being made where the semihigh-speed cathode breakers are eliminated and d-c relays tripping the anode breakers on overload are being substituted.

The authors describe how a cell or pot line is energized and de-energized by the use of igniter control. In case of rectifiers with continuous excitation, a pot line is started up by first applying blocking voltage to all grids, then establishing excitation and closing anode and cathode breakers of all units supplying the pot line. The load is then picked up by releasing simultaneously all the grids through a master contactor. A pot line is de-energized in the same manner as described in the paper, that is, by simply tripping all cathode breakers from a common trip switch.

The paper deals exclusively with the intermittently excited, ignitron-type rectifier. The application data given in the paper naturally also hold good for the continuously excited single-anode rectifier, which, like its predecessor, the multianode rectifier, maintains an auxiliary arc as long as the unit is on the line.

Interim Report on Guides for Overloading Transformers and Voltage Regulators

Discussion and author's closure of paper 42-156 by the AIEE transformer subcommittee of the committee on electrical machinery, presented at the AIEE summer convention, Chicago, Ill., June 22–26, 1942, and at the AIEE Pacific Coast convention, Vancouver, B. C., Canada, September 9–11, 1942, and published in AIEE TRANSACTIONS, 1942, September section, pages 692–4. This discussion was presented at the Pacific Coast convention.

J. E. Clem (General Electric Company, Schenectady, N. Y.): The war emergency has focused attention upon the problem of overloading electric equipment as an aid to winning the war. The interest in this problem is based upon either a desire for immediate increased power output or upon the hope of saving critical war materials.

Whenever overloading of equipment is necessary to meet a rising war load requirement, such overloading should be done, provided that the added load does not cause the equipment to fail within the period of its vital war need. If the desire is to save critical war materials, a great deal may be accomplished by the use of new and modern system layouts, by a more accurate predetermination of the required load, and by the adoption of new and modern practices.

The output rating of transformers is based upon a definite temperature rise under specified testing conditions. The temperature rise upon which the rating is based has been selected from consideration of the maximum temperature at which the insulation of the transformer may be continuously operated and still achieve a reasonable life expectancy, together with the anticipated ambient temperature in which the equipment may operate.

The maximum continuous temperature for a reasonable life expectancy has been taken as 95 degrees centigrade; the temperature rise has been set at 55 degrees centigrade with a hot-spot allowance of ten degrees centigrade above the average temperature rise or a hot-spot temperature rise of 65 degrees centigrade. Then the condition that normal life expectancy be based on continuous operation at 95 degrees centigrade, together with the condition that the output be based on a hot-spot temperature rise of 65 degrees centigrade (average temperature rise of 55 degrees centigrade plus ten degrees centigrade allowance for hottest spot), establishes a continuous temperature of 30 degrees centigrade as the reference ambient for normal life expectancy. Estimates for the effect of varying ambient temperatures upon the life expectancy should, therefore, be made using 30 degrees centigrade as the reference ambient at which normal life may be expected.

It is pertinent to review the basis upon which the estimate of the effect of overload on the life of transformers is made. The useful life of class-*A* insulations, such as is used in transformers, is dependent upon the temperature to which the insulation is subjected. However, it should be fully realized that laboratory tests upon which estimates of the life of transformers are based are tests of a mechanical nature. In these tests, the loss in tensile strength after exposure to a definite temperature for a definite time is determined under very carefully controlled laboratory testing technique. There is a broad spread in results of such tests from different sources. The correlation between the life expectancy of transformer insulations as indicated by laboratory tests and the actual life of a transformer is largely a matter of speculation. Therefore, all estimates of the effect of overload upon the life of transformers must be tempered by sound judgment based upon operating experience.

H. K. Sels (Public Service Electric and Gas Company, Newark, N. J.): In New Jersey we have been following the procedure of operating transformers according to temperature for some time, but we have been puzzled with the practical means of instructing operators of average intelligence to handle such a technical question. In this connection, I am impressed with the data and curves presented in the interim report. In practice, short-time overloads cannot be used as such, because when the emergency arises no one knows how long it will last, nor whether a high overload should be carried for a short time, or some load dropped and a smaller overload carried for a longer time. This is particularly true when maintenance men are off duty and are difficult to get on duty to cut spares into service. Therefore, I should like to suggest to the transformer subcommittee that these technical data be put into shape to be used directly by operating personnel.

We have been experimenting with the possibility of expressing overload rating as a relationship between top-oil temperature, time, and load, so that the operator, by reading the top-oil temperature at the time of the emergency, will know from a curve the overload which can be carried. Then, as the top-oil temperature rises, the overload must be reduced until finally the overload is almost back to normal with the maximum permissible hot spot.

Another question which has perplexed us is: "When is a transformer forced air cooled?" Of course, we appreciate the fact that each manufacturer likes to install his particular air-blast equipment in his own make of transformers. However, we find that ordinary blowers or fans separated from the transformer are quite effective. Transformers are installed initially without fans, and then fans are added later. After an additional transformer is installed, fans are not needed for a period and can be used elsewhere. Therefore, the program alter-

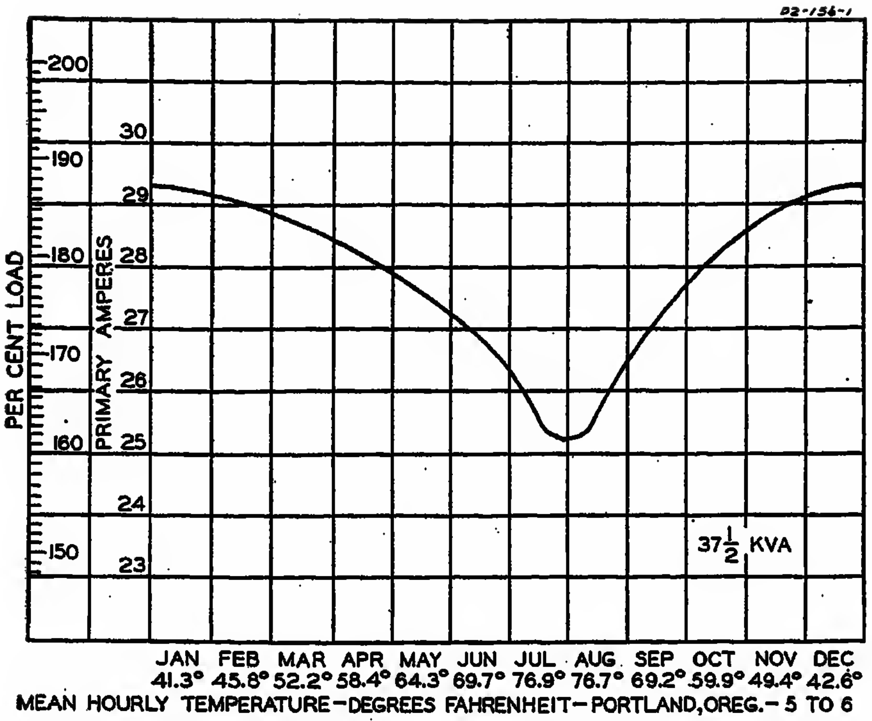

Figure 1. Maximum permissible load in per cent and primary amperes versus months of year (if not limited by voltage regulation)

A $37^1/_2$-kva 2,400/120–240-volt single-phase overhead distribution transformer. Based on 50 per cent initial load followed by a two-hour peak period. Curve represents points at which the carrying charges on the investment and loss in life plus core and copper losses of a $37^1/_2$-kva transformer equal the carrying charges on investment, loss in life, and installation cost plus core and copper losses of a 50-kva transformer plus carrying charges on the removal cost of a $37^1/_2$-kva transformer. Carrying charges are 14 per cent per year. Core and copper losses amount to two mils per kilowatt-hour. Loss in life is based on study by L. C. Nichols[1]

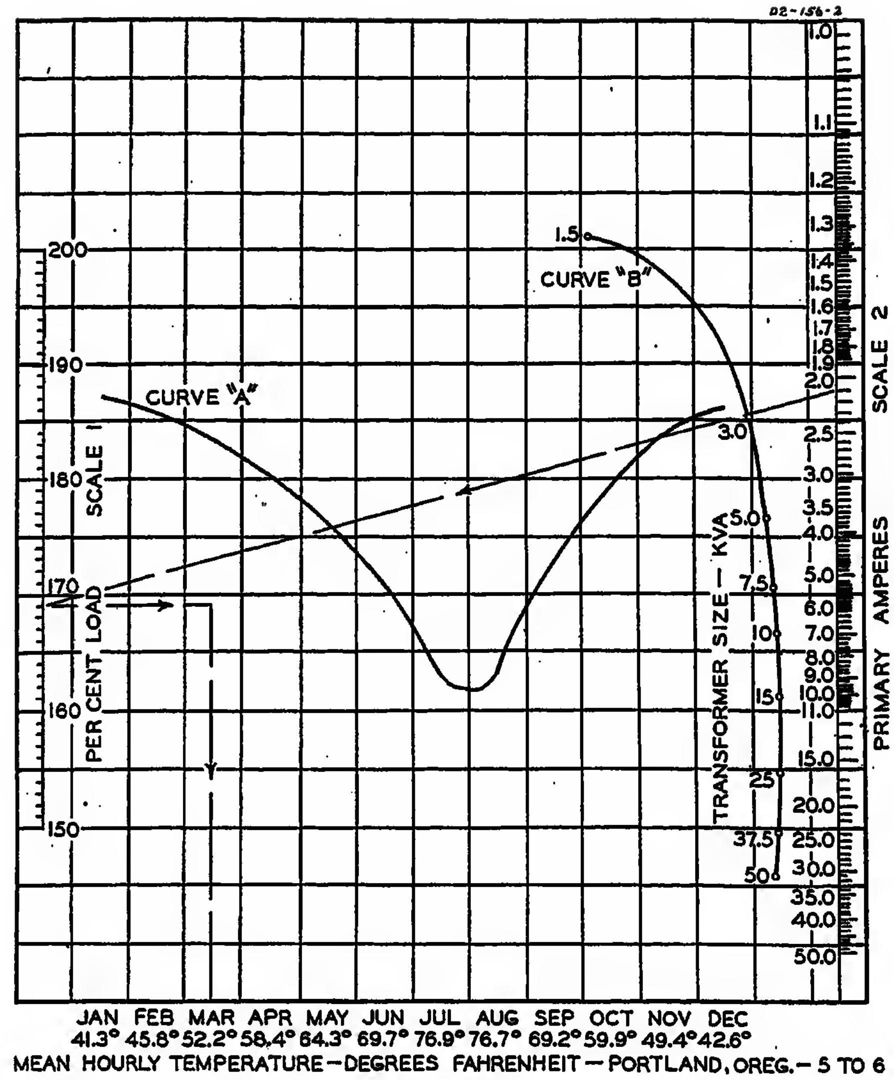

Figure 2. Maximum permissible load in per cent and primary amperes versus months of year (if not limited by regulation)

2,400/120–240-volt single-phase overhead distribution transformers. To find if 2.1 primary amperes on three-kilovolt-ampere transformers exceed maximum permissible loading in the middle of March, project a line from 2.1 on scale 2 through three kilovolt-amperes on curve *B* which indicates a 169 per cent load on scale 1. From the latter point project a line horizontally toward curve *A* to the period of the month (shown below curve *A*) in which test was made. The horizontal line from 169 per cent terminates below curve *A*, showing that maximum permissible loading has not been reached. To determine the limit of loading, project a line vertically upward from the middle of March to curve *A*, which shows 183.5 per cent or 2.3 amperes

nates between fans and additional transformers, as the load grows, so that mobile fan installations constitute the most acceptable fan cooling.

Corbett McLean (Northwestern Electric Company, Portland, Oreg.): The interim report, by the transformer subcommittee, on overloading of transformers and regulators is a pertinent one in these times of emergency when every ounce of copper and steel should be loaded to the fullest capacity.

For some time, we have been using curves on permissible transformer loading for our overhead 2,400-volt distribution transformers. A combination curve is shown in Figure 2, and an individual curve for a $37^1/_2$-kva transformer is illustrated in Figure 1.

These curves give the maximum permissible economic loading for ambient temperatures during each month in the year and represent points at which carrying charges on investment, loss in life, and total transformer losses are equivalent to the carrying charges for the same items for the next larger size transformer plus the removal cost on the old transformer. They are based on a 50 per cent initial load followed by a two-hour peak period. Naturally, ambient temperatures, load curves, carrying charges, installation and removal costs, costs of power, and so forth, will vary considerably with other companies, and some will vary for any given company. However, the curves provide some reasonable and simple method of rapidly determining the point at which a transformer should be replaced.

During the present emergency we believe that these curves should be materially exceeded with the realization that life expectancy will be greatly reduced.

Our past experience has led us to permit a greater loading for induction voltage regulators than for distribution transformers. The carrying capacity of current transformers, cable, disconnecting switches, and so forth has generally been the limiting factor on primary feeders.

We have used water spray for some time on 5,000- and 2,000-kva single-phase 66,000/11,000-volt transformers to provide for overload capacity and have found the main drawback to be the frequent painting required on case and tubes.

We appreciate the value of this paper on transformer and regulator loading. It is most opportune and provides a standard which can easily be applied by all in the operating field.

1. Effect of Overloads on Transformer Life, L. C. Nichols. AIEE Transactions, volume 53, 1934, December section, pages 1616–21.

C. T. Hurd (Allis-Chalmers Manufacturing Company, Milwaukee, Wis.): No one will deny that the present war emergency is going to make it necessary, in many cases, to operate transformers at an overload, but what will probably be overlooked is the premature aging of the transformer insulation from operation at these overloads.

The data brought out in the interim report showing allowable overloads are, I understand, based on the supposition that these emergency overloads will not be recurrent in nature. The basis for the report is therefore the assumption that transformers will be necessarily overloaded, but that means for relieving these overloads or for eliminating the necessity for such overloads will be promptly taken.

The term, "reasonable loss of life," is, according to my understanding, intended by the committee to mean a loss of life not to exceed one per cent, and, obviously, if an overload condition is recurrent with a loss of life of one per cent every time it occurs, the full life of the transformer insulation could be readily expended in serving the overload, unless prompt relief is provided.

Since it has been common operating practice in the past to operate power trans-

formers at loads below their name-plate rating, and, since depreciation rates have been predicated on past operating experience, it could be easily overlooked that the cost of supplying any load, which results in overloading of power transformers serving it, will be considerably higher than normal, since the overload will result in an accelerated depreciation rate or, in other words, in a shortened transformer life. In addition, of course, other increased costs must be met, including the cost of supplying increased losses to the overloaded transformer, the effect of increased regulation of the overloaded transformer, and other factors of this nature.

Insulation in transformers does age and tends to become brittle at any operating temperature. When transformers are operated below their name-plate ratings with usual ambient conditions, insulation deteriorates at a very slow rate so that the life of the transformer is very long. Any overloads, even within the limits suggested by this report, simply mean that the life of the transformers affected will not be as great as it would have been with past normal operation, and, while it is entirely possible that no noticeable increase in the failure rate will occur during the emergency, this increased failure rate will probably have to be met later.

Transformer insulation ages by becoming brittle, and brittleness produced by transformer overload carried during the present emergency will persist throughout the entire life of the transformer. The creation of brittleness in transformer insulation obviously lessens the mechanical life of the transformer insulation, and movement of the transformer windings from any cause will be more apt to result in failure than would be the case if the transformer insulation were in normal condition. Under present conditions, overloads are doubly serious because of the rising system load factors. Overloads which follow light load conditions naturally will not result in so much loss of life as will prevail in most instances now, since most systems are operating under greatly increased normal loading. Even without the overloads, transformer copper and oil temperatures will follow a higher average value; consequently any overload which can be carried will of necessity be of shorter duration if serious loss of life is to be avoided.

It is particularly interesting to note in passing that the curves presented in this report coincide rather closely with data presented in one of the earliest papers ever written on the effect of overload on transformer insulation, namely, that by the late L. C. Nichols, entitled "Effect of Overload on Transformer Life"[1] and presented before the Institute's winter convention early in 1935. Much work has been done on transformer insulation since that date, but the figures on insulation loss of life used by Mr. Nichols are well supported by this paper.

As previously stated, it will be impossible to avoid all power-transformer overloads, but the cost of such overloads from such factors as loss of life, increased losses, and so forth, will ultimately have to be met.

M. S. Oldacre: We believe that the statements in the third and fourth paragraphs of Mr. Clem's discussion should be considered as his own interpretation of the American Standard *C*-57, "Standards for Transformers," in regard to normal ambient temperature, hottest-spot temperature, and life of insulation. This portion of his discussion has no bearing on the interim report, since the temperatures discussed do not appear in that report. Also we believe that Mr. Clem's interpretation of American Standard *C*-57 is not that generally accepted by the committees which prepared the standards and the interim report.

Ignitron Rectifiers in Industry

Discussion and author's closure of paper 42-118 by J. H. Cox and G. F. Jones, presented at the AIEE summer convention, Chicago, Ill., June 22–26, 1942, and at the AIEE Pacific Coast convention, Vancouver, B. C., Canada, September 9–11, 1942, and published in AIEE TRANSACTIONS, 1942, October section, pages 713–18. The following discussion was presented at the 1942 Pacific Coast convention.

J. H. Steede (British Columbia Electric Railway Company, Ltd., Vancouver, B. C., Canada): The expansion of the electrochemical industry has provided an enormous field of application for the mercury-arc rectifier, as the authors of this paper have pointed out. It is exceedingly interesting to note the tendency toward single-anode tanks in the general field of rectifier design on this continent. This design appears to be a definite improvement over the multianode metal-tank type for all classes of application, because of the more exact control of the ignition point, the extinguishing of the arc during the time that reverse potential is applied to the anode, which reduces the likelihood of back-fire, and the lower internal voltage drop which results from the shorter arc path.

Two characteristics of the multianode metal-tank rectifier are still retained, however, namely, the necessity for water cooling with possible attendant corrosion problems, and the need for occasional pumping to maintain vacuum. Both of these features add considerably to the amount of auxiliary equipment required with metal-tank rectifier installations.

The British Columbia Electric Railway Company has had a limited experience with rectifiers for traction purposes since 1929, when a 1,000-kw 12-anode metal-tank unit was placed in service. Operating experience with this unit was disappointing. In 1936 a new tank assembly was provided, which, with close control of the cooling-water temperature, has given satisfactory service since that time.

Three more recent installations have been of the glass-bulb multianode type, consisting of two two-bulb units and one four-bulb unit, the rating of each bulb being 165 kw at 550 volts. Some data relative to these installations may be of interest.

One of the two-bulb installations has been in practically continuous service since December 1936, with only two or three short outages, caused by a-c power failure.

A similar installation made in 1937 has almost as good a service record, although this unit was put out of action on one occasion as a result of a lightning stroke on the trolley in the immediate vicinity of the substation which presumably caused the rectifier to backfire, blowing eleven of the twelve anode fuses with which this unit is equipped. These fuses were replaced and the unit returned to service without further servicing.

The four-bulb unit, which was installed in 1938, apart from occasional cleaning, has been out of service only for short periods during temporary failure of a-c power supply.

All of these units are in unattended substations, and the maintenance costs have been extremely low. One man's time for approximately two days per month has been ample for maintenance purposes, and of that time only approximately one-half day per month is actually spent inspecting and servicing the equipment.

Lysle W. Morton (General Electric Company, Schenectady, N. Y.): This paper, entitled "Ignitron Rectifiers in Industry," covers in a very satisfactory manner conventional large power installations. In general, most of the installations which have been recently made conform to the rules of application described in the paper.

However, there is one feature described, namely, water cooling by means of copper tubes soldered on the walls of the tanks, which is often accomplished otherwise.

Early experience with water-cooled mercury-arc rectifiers indicated that the direct use of most raw untreated tap waters caused corrosion of the steel vacuum chambers. Manufacturers and users immediately set about to search for a solution for that problem. Early in the 30's two satisfactory answers were found:

1. The use of noncorrosive metal surfaces in contact with the cooling water, such as copper or stainless steel. One of these the authors describe.
2. The use of sodium chromate or dichromate as a rust inhibitor.

The second method is also widely and successfully employed. A water-to-water, or water-to-air heat-exchanger system must be used, because it is necessary to recirculate the treated cooling water. The recirculating coolant is treated by adding either enough sodium dichromate to provide a 0.5 per cent solution or enough sodium chromate to make a 0.1 per cent solution.

Inspection of water-cooled surfaces of rectifiers which have been in contact at high temperature with treated waters for many years proves that it is a most successful rust inhibitor and a satisfactory application.

Still another advantage accrues from the use of sodium dichromate. Tests made on evacuated steel chambers, particularly if the temperature is elevated slightly, indicate hydrogen ion penetration of the steel envelope from either the surrounding air or from ordinary water if the chamber is water-jacketed. It was found, however, that the addition of sodium dichromate to the water eliminates this penetration and prevents contamination of the vacuum.

Using a solution of sodium chromate or dichromate as the recirculating coolant and employing the simple principle of an ordi-

nary steel water jacket around the vacuum changer secures the following advantages:

1. A greater part of the vacuum-chamber area contacts the cooling solution, which means better heat transfer and less chance of ion penetration from the air.

2. A severely restricted material is saved.

3. The recirculating coolant does not pick up products of corrosion, such as even untreated distilled water may, from the various odd ends of the cooling system. This is true, because even though copper may be used on the rectifier and the heat-exchanger surfaces, it is usually impractical to make the surge tanks, tube headers, and reservoirs of other materials than steel or iron.

4. There is no chance of deterioration of the rectifier equipment or blocking of cooling passages as a result of corrosion or products of corrosion.

It is sometimes desirable to ground the water-to-water heat exchangers to eliminate the inconvenience to personnel of having the heat-exchanger surfaces at various potentials above ground. This can be done both with the soldered-on copper tubing employing distilled water, or by using 0.1 per cent sodium-chromate solution, as the leakage currents are satisfactorily limited. However, if it is not too inconvenient, it is better to insulate the heat exchanger from ground and allow it to operate at rectifier potential. This has the advantage of keeping the leakage currents back to ground in the cooler and more highly resistant part of the water circuit where they can be minimized.

H. K. Sels (Public Service Gas and Electric Company, Newark, N. J.): Cox and Jones have dealt rather briefly with the problem of telephone interference. There are many other factors involved besides those mentioned, such as the susceptibility and configuration of the communication or signal system and the present influences and electrical characteristics of the power system. This problem cannot be dismissed lightly considering the inductive co-ordination measures usually present in every system where some additional influence such as rectifier harmonics may produce trouble.

The suggestion of the authors that 36-phase operation gives satisfactory operation in most cases raises two questions:

1. Speaking in general terms for average conditions, what proportion of system load can rectifier load become before trouble will be experienced?

2. Have there been any cases where more than 36-phase operation has been required?

This is a question involving several parties; namely, the utility, their customer, communication or signal interests, and equipment manufacturers. From a utility standpoint, it is expected that the customer and the manufacturer of his equipment will be responsible for continuing good relations with communication and signal companies.

J. H. Cox: Mr. Steede has discussed glass-bulb mercury-arc rectifiers and has presented a case where they have proved satisfactory. However, it must be admitted that these large glass bulbs are inherently fragile wherever installed and are suitable at all only for relatively low-power installations. For large installations such as are common in the electrochemical industry the glass bulb has two very serious limitations:

1. The current per anode is low, and the number of main and secondary wires would be prohibitive.

2. On large busses high-speed switching is necessary to avoid destruction of apparatus, and the cost of high-speed switching would be prohibitive for even the largest glass-bulb rectifiers.

Mr. Morton has discussed the use of ordinary steel water jackets on the rectifier, together with sodium-dichromate treatment of the recirculating water. It is true that this system is also quite satisfactory. I question the statement that there is hydrogen-ion penetration through the steel where exposed to air. Such penetration would depend upon some corrosion taking place, and, obviously, an exposed portion of the tank would be finished to prevent such corrosion. The only functions of cooling are to dissipate the losses and to maintain a mercury vapor pressure which provides satisfactory rectifier performance. Since this performance actually is highly satisfactory with soldered-on copper cooling coils, there can be little argument about the effectiveness with which such a system cools the tank walls. Furthermore, where copper is used on the rectifier the extent of corrosion that takes place is purely nominal in a recirculating system where oxygen is excluded, even on the portions of the circulating system that must still be made of iron. It will be agreed generally that the grounding of a piece of apparatus is always desirable, and the sodium-dichromate treatment of the recirculating water certainly increases the difficulty of grounding the heat exchanger.

Mr. Sels discusses the question of harmonics generated by large rectifier installations and asks what proportion of system load can rectifier loads become before trouble will be experienced. There are several installations where the rectifier load constitutes practically the entire generating output. In at least one case this local system, involving over 100,000 kw, is connected to a public-utility transmission system, and no difficulty has been experienced. In the Bonneville territory the rectifier load is becoming a very important percentage of the total. Although no serious difficulty has been encountered, the sheer magnitude of the powers involved in this location has caused at least one user to decide to increase the number of phases to 108 at those stations where this is possible.

Three-Winding Transformer Ring-Bus Characteristics

Discussion and authors' closure of paper 42-153 by G. W. Bills and C. A. MacArthur, presented at the AIEE Pacific Coast convention, Vancouver, B. C., Canada, September 9–11, 1942, and published in AIEE TRANSACTIONS, 1942, December section, pages 848–9.

A. H. Frampton (The Hydro-Electric Power Commission of Ontario, Toronto, Ont., Canada): The type of switching diagram proposed by the author is one which, in slightly different form, has been proposed for several major developments in eastern Canada. The selection of a proper diagram in such cases is often difficult, and it has been found helpful to draw up the following specification for an ideal diagram against which alternative proposals may be compared, and their relative merits weighed. Probably no one diagram will ever meet all of these requirements, but at least the exercising of personal judgment may be limited to the weight accorded each item in the specification.

1. The switching diagram should be sufficiently flexible to permit the available capacity being subdivided into as many components as there may be independent groups of load to be supplied, while retaining:

(*a*). Convenient and flexible control of real and reactive power flow in each load subdivision.

(*b*). The ability to isolate any piece of equipment, in event of disturbance or for purposes of routine maintenance, without affecting other equipment which should remain in service.

At the same time the highest practical efficiency of operation should be effected in the combined plant, whether measured in terms of utilization of river flow or fuel consumption.

2. The clearance of any disturbance in any one load subdivision should not affect the continuity of service in other load subdivisions.

3. The loss of one transmission circuit in any one load subdivision should not isolate from the load generating capacity in excess of the operating reserve capacity in that load subdivision.

4. The operating duty imposed upon both new and existing circuit-breaker equipment should not exceed the safe capacity of such equipment.

5. The diagram should be simple, preferably symmetrical and of a repetitive form, so that the switching connections in each of the load subdivisions will resemble each other and also the combined station diagram. Undue complexity that would hamper the operating staff, particularly under emergency conditions, should be avoided.

6. The over-all cost should compare favorably with alternative proposals.

As the diagram shown in Figure 2 of the paper is presumably not advanced as a practical proposal, but only as representing any form of diagram resulting in bussed connections at the sending and receiving ends, no comments are offered beyond the fact that a saving in low-voltage bus copper, and some reduction in short-circuit values would result from the use of conventional double low-voltage windings in the step-up transformation. However, if the diagram proposed in Figure 1 of the paper is judged on the basis of the above specification, it will be noted that it will rank high only if it is granted that the station will always supply only one load group. In that case, all but two of the conditions will be satisfactorily met, the exceptions being that all breakers are inaccessible for maintenance work without the associated equipment being taken out of service, and the over-all cost is likely to be high.

In the latter connection, the author refers to the additional cost of the increased step-up transformer capacity as being partially offset by the elimination of high-voltage breakers. Actually, if it is granted that in Figure 2 double low-voltage windings could have been shown, then the author's diagram requires at least double-capacity breakers and connections in the low-voltage transformer circuits, with a further consequent increase in cost. Approximate estimates would appear to indicate that the total increased cost could be offset only if the transmission voltage were considerably higher than 230 kv, thus effecting a very substantial saving in high-voltage switching. In the optimum case, it is possible that the author's proposal might result in the saving of one complete transmission circuit.

On the other hand, if it is required that

the station illustrated be subdivided into two load groups, or say a nine-unit station into three groups, it will be noted that it will be extremely difficult to satisfy the requirements of condition 1 in the preceding specification, even though additional connections are added to form further loops in the low-voltage circuits. If these connections are added, then the diagram becomes quite complicated, conflicting with condition 5. It is considered therefore that this form of diagram would find application only in single-load group generating stations or their equivalent.

H. N. Muller, Jr. (Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa.): The authors have described the results of an a-c network-calculator study performed to investigate the merits of a particular generator bussing scheme. This ring-bus arrangement was studied over 15 years ago at the time the Boulder Canyon project was under consideration, but results of such studies have never been presented in the technical literature. The investigation performed by the authors shows that application of this bussing arrangement results in increased transient power limits and decreased short-circuit currents, both of these attributes being of prime significance on certain systems.

The authors chose for study a ring-bus system composed of four groups of two generators connected through three-winding transformers to four high-voltage lines. All these lines terminate on one load bus. Since each generator is specified to have a capacity of 55,000 kva, this means that the total output of the assumed station, 440,000 kva, is transmitted to one load center. This is not improbable, but the more usual case would be for these transmission lines to carry the station output to two or more load centers. In the introduction to this paper, power concentrations of over 1,000,000 kw are directly referred to, and in developments approaching this size it would be extremely unlikely to have the entire output delivered to one load bus. As a matter of interest, the authors name Boulder Dam, Grand Coulee, and the proposed St. Lawrence project as exemplifying large power concentrations where the bussing scheme studied might be of advantage. Note that none of these projects named do, or probably would, deliver their total output to one load center.

The question then naturally arises as to whether the smaller ideal system chosen for study by Bills and MacArthur can be used to reach conclusions that can be extrapolated to apply to the larger and more general layouts. With this point in mind the discusser has performed additional studies of a more general nature, concerning the results of which brief comments are offered.

If a larger generating source is assumed than that chosen by the authors, and if the transmission lines emanating from this source are of varying length and deliver load to two or more independent load centers, the three-winding transformer ring-bus scheme becomes less ideal. Significantly higher transient-power limits and lower short-circuit currents still prevail, but other operating limitations can appear. If one independent load center is drawing heavy load, while the load supplied over other lines to another receiver is light, unbalanced division of the reactive kilovolt-ampere burden between generators will result, and one or more generators may exceed their maximum field limitations while other units operate with light field current. To alleviate this difficulty it would be necessary to sacrifice bus voltage regulation. If it is desired to control the voltage of the transmission lines feeding one load center independently of those lines feeding another receiver, the proposed ring-bus arrangement appears inflexible compared to certain more conventional schemes.

The above points are not mentioned with an intent to condemn but are raised to show that the bussing scheme in question requires careful study before its use is recommended for a particular installation. Very broad conclusions cannot be drawn from study of one system. On systems embodying the comparative simplicity of the one studied by the authors, this transformer ring-bus arrangement appears to offer valuable advantages without introducing any difficult problems of operation. It deserves serious consideration on projects whose complexity is limited by size but of necessity must be carefully analyzed on large projects, since the operating problems and limitations which can result may overbalance the inherent advantages.

G. W. Bills and C. A. MacArthur: It is granted that the three-winding ring-bus arrangement is not a cure-all, but no known system will satisfy all the requirements specified by Mr. Frampton. To bus as much as 1,000,000 kva of generators at a station is not only risky in that the entire station may be lost during a disturbance, but problems involving the control of real and reactive power flow may arise when different load groups exist. For this reason we consider only single-load systems although more extensive systems have been investigated and found feasible.

Mr. Frampton stated that only the use of transmission voltages higher than 230 kv would offset the increased cost of larger transformer capacity. We would like to point out that it is permissible to invest more in the three-winding transformer ring-bus system than in the sandard system because of the increase in firm power it is possible to transmit. However, an economic study was beyond the intended scope of this paper.

From transient-stability and short-circuit considerations, however, the three-winding transformer ring-bus system has been shown to have very definite advantages.

It is extremely interesting to know that Mr. Muller investigated the ring-bus arrangement years ago and arrived at the same conclusions as the authors concerning the stability and short-circuit considerations.

We would like to point out that the output of six 82,500-kva generators at Boulder Dam sends power to a common bus at Los Angeles; that in the proposed St. Lawrence project as much as 500,000 kw may go to Rotterdam, N. Y.; and in the Bonneville Power Administration transmission system similar blocks of power will be transmitted to concentrated load centers such as at Seattle, Spokane, and Vancouver, Wash.

Any scheme which busses all the generators will be inflexible when it becomes necessary to regulate different receiving-end bus voltages by changing the sending-end potential. However, most modern hydroelectric projects resort to the use of synchronous condensers and transformers having tap changing under load for purposes of regulation so that this is not a serious problem.

Mr. Muller's point that this ring-bus arrangement must be carefully analyzed for a particular system is well taken. We did not intend to imply this bussing arrangement was suitable for *all* large systems but had hoped to show it might be very suitable for certain projects.

A Practical Discussion of Problems in Transformer Differential Protection

Discussion and author's closure of paper 42-146 by P. W. Shill, presented at the AIEE Pacific Coast convention, Vancouver, B. C., Canada, September 9–11, 1942, and published in AIEE TRANSACTIONS, 1942, December section, pages 854–8.

John Teasdale (British Columbia Electric Railway Company Limited, Vancouver, B. C., Canada): There are two paragraphs near the beginning of this paper which, in generalizing on current-differential schemes, seem to suggest that various measures used to secure good balance on differential circuits no longer have the same value as formerly. This view is scarcely in accordance with the facts.

As experience is extended, and as larger units come into service, the trend is rather in the direction of still greater care in the application of current-differential protection and instances to the contrary imply the acceptance of a lower standard of engineering.

Accuracy in reproducing the primary conditions in the secondary circuits at all times is still the ideal sought after and is approached as nearly as possible on important installations. When all that is possible has been done in this direction, *then* consideration is given to dealing with inaccuracies that cannot be avoided, so that they do not affect relay operation adversely.

A high-setting instantaneous relay combined with a low-setting timed relay, as referred to in this paper, is one method of evading trouble on account of these causes, but it should not be regarded as modifying the need for a good balance in the secondary circuits. Otherwise, to be entirely safe, it will require settings that involve material sacrifice in speed or sensitivity. For this reason, its value on installations of any importance, without any additional protection, is likely to be inferior to ordinary differential protection using restraint on through faults, and these relays cost little more and are probably no more difficult to obtain in wartime.

E. G. Ratz (Canadian Westinghouse Company, Ltd., Hamilton, Ont., Canada): Induction-type relays having very inverse

characteristics, with fairly sensitive current settings and a high-speed instantaneous trip device included, are difficult to improve upon for transformer differential protection.

The maximum through-fault current can usually be determined from the reactance of the transformer bank, and the difference currents in relays can be reduced to a minimum on through faults by exact matching of the current-transformer ratios. We have found this to be a very desirable procedure in order to make such difference currents a minimum and thus reduce this limitation to the permissible sensitivity setting. If proper care is taken, difference currents on through faults will certainly be small, and, even if they do exceed the current setting of the relay-induction element, faulty tripping will almost certainly be avoided because of the difference currents being such as to cause the relay to operate on the inverse and longer timed portion of its curve.

Difference currents on through faults are also minimized by keeping the burden on the main current transformers at a minimum, and this makes the omission of auxiliary balancing transformers desirable, as such transformers usually have a relatively high burden.

The current setting of 15 amperes and 15 cycles suggested for magnetizing inrush seems high. Even if the maximum inrush current considerably exceeds the current setting, this current falls very quickly, and a very inverse characteristic will prevent faulty operation. Further, relay elements of the induction type are less susceptible to difference currents with d-c components than plunger-type relays.

With respect to the author's objection to the use of suppressor devices to prevent operation on magnetizing inrush, it is suggested that a relay of the ratio differential, or any other type, can have restraint added with a momentary compensating magnetic characteristic in proportion to the *rise* in voltage. This restraining action would be the maximum at the moment the transformer bank is energized and would die out at approximately the same rate as the magnetizing inrush, thus providing restraint only when required and approximately in proportion to the requirements at various moments during the magnetizing inrush period. If the transformer bank were picked up with a fault, the fault-current torque would exceed the restraining coil torque within a cycle or two, providing the required operation without undue delay.

We have used impedance relays, with the current coils connected in the differential circuit, and the voltage coils energized from the main circuit and set to operate instantly at a differential current of approximately three times full load current, at full voltage. In case of bad faults, the voltage drops, thus reducing the differential current required to trip, in proportion to the drop in voltage. This relay is more sensitive on faults than a straight instantaneous overcurrent relay and is particularly effective and fast if the transformer bank is large compared to the connected system, for example, if the fault current delivered to the transformer bank is unusually low because of reduction of connected capacity.

We feel that it is highly desirable to provide devices to limit the sensitivity momentarily to meet inherent conditions such as magnetizing inrush, and through-fault currents, if necessary, rather than to reduce the sensitivity of the equipment under all conditions.

L. L. Fountain (Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa.): The subject paper calls attention to some very important considerations in the differential relaying of transformer banks. The admonishments in regard to washing out zero-sequence currents, where the transformer bank is grounded, and the methods used in calculating ratio of current transformers are adequate.

I feel, however, that not enough emphasis has been placed on the calculations necessary to obtain the transient values mentioned under the heading "Relays." In order to arrive at the assumed values given for maximum differential current caused by through- and magnetizing-current transients, a rather complicated set of calculations must be made, requiring a knowledge of the current transformer's saturation characteristics, time constants of the system, and relay characteristics when energized by transients containing a large d-c component. Probably Mr. Shill considered that the practical nature of his paper did not permit delving too much into these calculations. Mention of them, however, would prevent any false notion that the values he gives are readily available on the majority of applications.

The percentage differential relay with restraint windings is certainly to be preferred over and above the simple overcurrent relay. This type of relay permits the use of current transformers that are not evenly matched so far as saturation characteristics are concerned. Also the complicated calculations necessary in the application of the simple overcurrent relay can generally be omitted when the percentage differential relay is used, since its restraint characteristic allows a larger differential current to flow without false operation.

The percentage differential relay used in transformer protection is of the same construction as the induction time-delay overcurrent relay recommended in this paper. Because of its popularity and the similarity of its parts to those used in the induction overcurrent relay, it can be obtained from the relay manufacturers as readily as any other relay.

The discussion of magnetizing-current inrush trip suppressors seems to deal only with those types that depend on time delay or shunting the relay operating coil to prevent false operation. There is available a type of trip suppressor that has none of these undesirable characteristics but depends on system voltage indication as a monitoring means to prevent false relay operation. A breaker closing to energize a transformer bank normally applies full voltage across the windings. If these voltages are normal, then the trip suppressor prevents the differential relay from operating on the magnetizing-current inrush. Should the transformer be faulted, then one or more of the three-phase voltages will be below normal, and the trip suppressor will allow the differential relay to function in a normal manner without time delay or decrease in its sensitivity.

S. Minneci (General Electric Company, Pittsfield, Mass.): In his discussion of the problems in transformer differential protection Mr. Shill describes a practical solution for the protection of power transformers with *fixed* ratios. Transformers equipped with load ratio control have their ratios changed by taps in any of their windings. A *variable-ratio* transformer will therefore allow an unbalance of 10 to 20 per cent in the secondary currents of differentially connected current transformers, in its leads. Since the unbalanced current thus produced does not increase greatly as a percentage of the through current, percentage differential relays in which the operating current is a certain percentage of the through current are usually employed to obtain a sensitive setting at low currents without danger of tripping the transformer breaker on through faults. This problem was the subject of an article written by J. W. Dodge and published in the May 1929 issue of the *General Electric Review.*

Another consideration in the problem of differential relay protection is the effect on the duration of inrush currents when transformers are paralleled. Studies made by C. D. Hayward, relay engineering department, General Electric Company show that inrush currents appear in both the transformer which is to be energized and the transformer already in service and that the inrush currents may persist at nearly full-load current magnitude for a period of 66 cycles after the second transformer is connected in parallel. Factors affecting the inrush currents and a means for adequate protection under these conditions are described in a paper prepared by Doctor Hayward.[1]

1. Prolonged Inrush Currents With Parallel Transformers Affect Differential Relaying. C. D. Hayward. AIEE Transactions, volume 60, 1941, pages 1096–1101.

P. W. Shill: While the paper was intended originally to deal with the subject of the present exigencies and the limitations in the selection of relays and other equipment which have been imposed on protection engineers by our governmental regulations, the discussion has tended more to the consideration of ideal conditions and designs.

The exact matching of current transformers to suit the inherent ratio of the power transformers presupposes that there be a series of taps on one set of current transformers to match the taps on the power transformers for the ratio-adjusting or tap-changing switchgear. While it may be quite easy to make changes in the cases of off-load ratio adjustments, it would be necessary to provide tap-changing switchgear for the current transformers in the case of automatic tap changing on load. This is hardly feasible economically; neither is it necessary, because small permanent differential currents can be taken care of easily. Slight differences in current-transformer ratios are no more serious in the cases of transformer banks with fixed ratios than they are in the cases of those with automatically variable ratios.

It is true that auxiliary current transformers usually have rather high burdens; in fact, most of them have burdens which

are considerably higher than they need to be. The errors they may intoduce are most serious in the cases of through-fault currents. In these cases the burdens of auxiliary current transformers are shared by two of the sets of power current transformers in the differential system. While the portions of the total burden of the auxiliary current transformers which are carried by each set of power current transformers may still be high enough to impair the ratios of the latter, both sets will be subject to the same conditions so that any differential between their secondary currents under these conditions will be relatively small. The chief objection to auxiliary current transformers is that they may provide additional d-c transients under fault conditions. The relays must be arranged to pass these transients. In the case of faults in the differentially protected zone, the auxiliary current transformers, by upsetting the ratio of one set of power current transformers, tend to make the protection more sensitive.

The calculations of expected transients were considered to be outside the scope of this paper, and they have been dealt with very well by other authors at different times. It should be noted that the figures given in the paper cannot be considered as typical by any means. Each case must be carefully considered on the conditions to be met, if there be any uneasiness of mind about transient conditions to be expected, or experience proves that such transient currents do reach troublesome values in any particular case. The case reported verbally at the convention meeting of a transformer bank having a charging current inrush of five times normal full-load current and requiring 2.5 seconds (150 cycles) to decay, shows what can be expected in extreme cases.

There is no argument that restrained relays which drop their restraint under fault conditions in the protected zone are very desirable and should be used if possible. From the writer's experience, current-ratio differential relays requiring as high as a 50 per cent unbalance to operate are not so satisfactory for passing transient currents as are ordinary overcurrent relays.

With regard to the availablility of relays, the writer has just received three ordinary induction-type overcurrent relays with instantaneous attachments for which the order was placed over 11 months ago. Of course, the standard explanation is "priorities." This may be sufficient and quite satisfactory for the devotees of this new quasi religion, but it does not help the man with a job to do, who has to meet dates when apparatuses are required to be put into service. How long it would take to get any special types of relays is anybody's guess these days.

Anyone who has had experience in practical engineering design knows that in almost all cases, in all branches of engineering, pin-point accuracy seldom is finally attainable or necessary. After one has made the calculations for one's ideal design, one must immediately look around for the equipment and materials which most closely meet the ideal requirements. Equipment and materials usually have to be selected from standard sizes and available stocks and adapted for one's purposes. Special equipment is, usually, relatively quite expensive and is not often justified by engineering considerations. If one accepts the principle that lack of pin-point accuracy is proof of a low standard of engineering, then there is and has been very little high-standard engineering done in any branch of the profession. In the writer's opinion, high-standard engineering consists of:

1. Determining the ideal arrangement and conditions that are desirable.

2. Determining the tolerances that are permissible.

3. Selecting the equipment and materials which are most available and economical for the purpose.

Pin-point accuracy is no more necessary in a properly designed current-differential protection than in any other piece of engineering.

Method for A-C Network Analysis Using Resistance Networks

Discussion and author's closure of paper 42-149 by Waldo E. Enns, presented at the AIEE Pacific Coast convention, Vancouver, B. C., Canada, September 9–11, 1942, and published in AIEE TRANSACTIONS, 1942, December section, pages 875–80.

Mabel M. Rockwell (Lockheed Aircraft Corporation, Burbank, Calif.): The author of this paper deserves commendation for his ingenious application of the circuit theory to the solution of the always difficult network problem using the d-c board. This development should be of considerable practical value to utility companies, since most of them have d-c boards available for short-circuit studies, but comparatively few have a-c boards, and under present conditions the likelihood of obtaining such is undoubtedly remote.

In operating a power system practical questions of load distribution, substation location, and so forth, occur even more frequently than relay problems and in the past have often had to be solved by very approximate or laborious methods. While Mr. Enns' method is, of course, more laborious than the simple solution of using an a-c board, in the absence of the latter it presents a powerful and useful tool for solving many urgent problems with the equipment on hand.

V. B. Wilfley (Westinghouse Electric and Manufacturing Company, Seattle, Wash.): The author of this paper should be commended very highly for his development of the method he has described.

Heretofore, it has been considered necessary to use the a-c calculating board for the making of complicated system load studies. However, there are few such boards available, and the means of making use of the standard variable resistance d-c board, as described by Mr. Enns, is of decided importance.

In these times, the very best possible use of all system facilities is necessary, and load division studies are essential for best system operation. Practically every utility owns a d-c board, and a description has been given as to how it may be used to obtain valuable information.

In the past, the use of d-c boards has, generally, been confined to short-circuit studies. Even for this type of study, the results were subject to some error, because either the resistance had to be considered as negligible or, if impedance values were used, those in one circuit had to be assumed to be inphase with those of other circuits. The method covered by the paper will be much more accurate for all types of studies, as the resistance and reactance are used in their correct relationship to each other.

A review of the paper indicates that a certain amount of paper calculation work is necessary, but these calculations seem quite straightforward and involve only simple slide-rule mathematics. Also, such studies are not made frequently of a general rule.

In the first part of the paper, reference is made to a design of d-c board which will be particularly well suited for use with this method. It would be appreciated if Mr. Enns would give a little additional information about its general features and how it differs from the standard d-c board. I assume that it will make use of four circuits connected in series parallel to save time in obtaining readings.

Charles A. MacArthur (Bonneville Power Administration, Portland, Oreg.): One difficulty with Mr. Enns' proposal is the necessity for estimating voltages at points removed from the reference bus. The initial estimate should be relatively close in order to avoid the necessity for a second solution with the four network combinations (real and reactive current with resistance and reactance networks). For networks which are radically changed from any previously studied, this may be very difficult.

A short cut to obtain this initial result is possible by using the real component of current with the resistance network and the reactive component of current with the reactance network. These two combine to give nearly the correct magnitude of voltage drop to remote busses. The bus voltages thus obtained may be used as described by Mr. Enns in section 3 of the "Application of Method to Network Problems."

The use of resistance networks for a-c network analysis is a valuable tool for companies which cannot justify an a-c calculating board.

W. W. Parker (Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa.): Mr. Enns' paper is very interesting in describing an ingenious method of overcoming the inherent limitations of a d-c calculator board in the study of a-c networks. By successive solutions of four equations with four separate setups, the real and reactive power flow and bus voltages can be obtained.

As indicated in the paper, wherever a-c network calculators are available, they will always be used in preference to this method, as obviously the direct replica approach gives accurate solutions much more quickly and easily. For other than short-circuit or the simpler regulation problems, that is, for transient-stability and load-control interconnection problems, the application of the method discussed in the paper would be decidedly limited.

In the last few years, as outlined in the recent paper, entitled "The Modern A-C Network Calculator"[1] which was presented at the 1941 Pacific Coast convention, the number of a-c network calculators has greatly increased. The latter two, mentioned at that time as being under construction, have since been installed and are now in practically continuous operation.

Many of the a-c network calculators are available for use by engineers other than the owners, so that it is now possible for a-c calculator analysis of any of the major problems of the design and operating engineer.

Waldo E. Enns: The discussions presented indicate the acceptance of the method outlined in the paper as a practical tool for making load distribution and voltage studies with a d-c calculating board. This favorable opinion is appreciated, coming as it does from engineers close to the subject of a-c network analysis.

One point brought out in the discussion is that the use of this method applied to existing d-c boards is more laborious than the a-c calculator. This point must be admitted; however, where an a-c calculator is not close at hand, in many cases load studies can be solved more economically on an existing d-c board.

Although it was beyond the scope of the present paper, the writer hopes to describe soon a resistance board designed especially for this new method which greatly simplifies its use.

A New Single-Pole Service Restorer

Discussion and author's closure of paper 42-147 by E. E. Tugby, presented at the AIEE Pacific Coast convention, Vancouver, B. C., Canada, September 9–11, 1942, and published in AIEE TRANSACTIONS, 1942, December section, pages 889–92.

G. F. Lincks (General Electric Company Pittsfield, Mass.): Mr. Tugby has described a very interesting development in restorers or reclosers. One of the features of the restorer is the adjustability of time-current characteristics in the field, so as to trip at 150, 200, or 250 per cent of the rating within a variable time range of from about 2.5 to 9 seconds. While apparently desirable, there are some practical application problems which make the value of this feature somewhat questionable.

It is unlikely that many operators, even if they could, would consider throwing short circuits on their distribution systems in order to make the field adjustment Mr. Tugby states was necessary in properly co-ordinating the system described and shown in Figure 5 of the paper. In making system co-ordination studies for overcurrent protection, it is customary to demand a very high degree of reliability and accuracy in both the published time-current characteristics and the product. This permits making a completely co-ordinated system setup on paper with the expectancy of securing 100 per cent successful operation when installed. For example, a number of utilities with more than four years operating experience on sectionalized systems protected by single element and reclosing fuse cutouts report that they have yet to experience one false operation.

To make use of the adjustment feature of the restorer described for making a co-ordinated system setup on paper, it would be necessary to have a series of time-current curves such as is provided for relays. The time-delay adjustment of each restorer would have to be accurately calibrated for a number of intervening settings between the minimum and maximum so as to meet curves published for each one. Such a procedure naturally would involve some variables in commercial manufacture which would have to be known so they could be taken into consideration in making co-ordination studies. It would be of value if Mr. Tugby could give some data on just how much this variation would be. A comparison of the curves of Figure 2 of the paper when replotted on log-log co-ordinate paper shows a difference in shape between the maximum and minimum time delay. This would indicate the need for individual curves for each adjustment.

In setting up a co-ordinated system it is customary to start with the protective device farthest out on the system. The economic justification for the use of restorers or reclosers would be premised on services feeding appliance loads, such as ranges, and so forth, requiring at least 60-ampere service entrance fusing. As pointed out in the AIEE paper "Trends in Distribution Overcurrent Protection,"[1] in order for 60-ampere 250-volt fuses to operate ahead of the fuse on the primary circuit of the distribution transformer, the primary fuse link must be rated at least three amperes at 7.5 kv, five amperes at five kv, and 15 amperes at 2.5 kv. A majority of the restorers will be used with a minimum three-ampere fuse rating on 7.2/12.5-kv grounded-wye circuits. Thus, for example, proper sequence of operation with the 60-ampere service entrance and five-ampere primary fuses will require setting three-ampere restorers to trip at 250 per cent of the rating and with the maximum time delay. Progressive heating during the two subsequent closures cannot be depended upon to cause a higher rated fuse link to melt before lockout, since the seven seconds reclosing time of the restorers would permit too much cooling of this link. Some advantage might be gained from the adjustable feature if the restorers closer to the source of supply could be made to operate more slowly than the setting of the three-ampere restorer. But if the restorer at the extreme end is set at or close to the maximum tripping current and time delay, the desired number of restorers to be connected in series may restrict the permissible lower setting of the restorers closer to the source of supply.

The preceding illustration uses the three-ampere restorer as an example. However, other factors such as a "minimum fusing practice of five or eight amperes" at the transformer primary winding would preclude the use of a three-ampere restorer. Instead, a six-ampere restorer would be required with minimum 200 per cent and 250 per cent current pickup for five- and eight-ampere fuses respectively and with the maximum time delay. Transformers with internal fuses, especially the earlier product, might necessitate adjusting even 20- or 25-ampere restorers for maximum current and time-delay settings. Service experience has proved repeatedly that long-time outages amounting to as high as 12 or more hours may be anticipated if the transformer fuses and line-sectionalizing equipment are not co-ordinated properly.

In addition, economic considerations may dictate the use of single-element fuse cutouts at the branches. At many such installations fuse links will be employed which are rated higher than those just considered for transformer protection, thereby affecting the settings of higher-rated transformers. The AIEE papers, "Relative Value of Different Types of Overcurrent Protection for Distribution Circuits"[2] and "Relative Expense for Service Restoration With Different Types of Overcurrent Protection for Distribution Circuits",[3] as presented at the 1942 winter and summer conventions respectively indicate that in the general case single-element fuses provide the major portion of the improvement in service continuity that is obtainable by branch protection. Very little additional improvement can be secured by the use of either reclosing fuses or automatic-resetting reclosers or restorers. The savings in restoration expense were not proportional to the difference in initial cost of reclosing equipment over the low-cost single element fuses. This proportion would be further out of line if the adjustment feature added anything to the cost of the restorer.

It would appear, therefore, that the impracticability of making settings in the field and the application problems involved in co-ordination with fuses located farther out on the line definitely limit the advantage of the adjustability of the restorers' time-current characteristics.

If Mr. Tugby has any suggestions which will assist in making greater use of the adjustment feature of the restorer, they will be of value to those making system-co-ordination studies for overcurrent protection.

E. E. Tugby: Mr. Lincks apparently misinterpreted some passages of the paper when he assumes that it would be necessary to "throw short circuits on a distribution system" to determine restorer adjustments. It is customary to make system short-circuit studies before attempting any kind of co-ordination work, and the computed values are used directly for restorer settings.

On a test setup with five restorers in cascade, all operated 100 per cent correct after having been adjusted by lever setting.

Interpolation should be sufficiently accurate, if three time-current curves are available: namely, maximum, intermediate, and minimum time delay, with calibrated identification of the related points on the time scale.

Selective tripping is assured if time-delay settings between adjacent restorers of the same rating are 45 cycles or more apart. On 30-cycle settings occasional interference was observed because of manufacturing variations.

The assumption made by Mr. Lincks that installation of service restorers is only justifiable in certain highly loaded feeders does not stand up under practical scrutiny. The cost of replacing blown fuses is high no matter what the fuse rating.

Any computation of the economic justification of restorer installation on the basis of feeder size or length or on the basis of service improvement alone, without consideration of maintenance savings, must lead to erroneous results.

No one system condition can be labeled standard, and each requires special study, as any operating man knows only too well. That certain system setups exist which do not justify restorer installations is not disputed. In the majority of cases, however, their installation improves not only service continuity but also reduces maintenance costs, thereby justifying their application even if a moderate revision of fusing practice should be necessary in isolated cases.

History of A-C Wave Form, Its Determination and Standardization

Discussion and author's closure of paper 42-152 by Frederick Bedell, presented at the AIEE Pacific Coast convention, Vancouver, B. C., Canada, September 9–11, 1942, and published in AIEE TRANSACTIONS, 1942, December section, pages 864–8.

P. W. Shill (British Columbia Electric Railway Company Limited, Vancouver, B. C., Canada): Figure 1 of this discussion is a copy of an old oscillogram which is in the writer's possession. It was taken in the year 1908 at the City and Guilds of London Technical College, Finsbury, London, England, by Doctor Silvanus P. Thompson while demonstrating to his class the phase-angle shift of the current with respect to the voltage of a circuit under conditions of bad power factor.

Strangely enough Doctor Thompson was the author referred to by the author of this paper in reference 4.

The oscillogram, as can be seen by a close examination of Figure 1, was made on an "Ondographe Hospitalier." To the best of the writer's knowledge Hospitalier brought out this instrument in 1898. Quite probably it was the "electric curve tracer" which is referred to in the author's reference 17, to which is assigned also the date 1898.

For the benefit of those not familiar with the instrument, a brief description follows: The chart shown in Figure 1 was fastened around a brass drum. This drum was driven at a constant slow speed by a synchronous motor. The motor also drove a gear train which moved a contact around at another constant slow speed. A second contact was attached to the synchronous motor shaft. It can be seen readily that the two contacts would close the instrument circuit instantaneously, once for each revolution of the motor shaft, but never twice in succession at the same point on the a-c wave. This caused a pen, quite similar to the ones we have now on graphic instruments, to move backward and forward across the chart following the successive impulses received from the current through the advancing contacts. The wave traces have the same type of radial distortion with which we are quite familiar today on some types of graphic instruments; so that the chart was printed with one set of co-ordinate lines drawn radially, as can be seen.

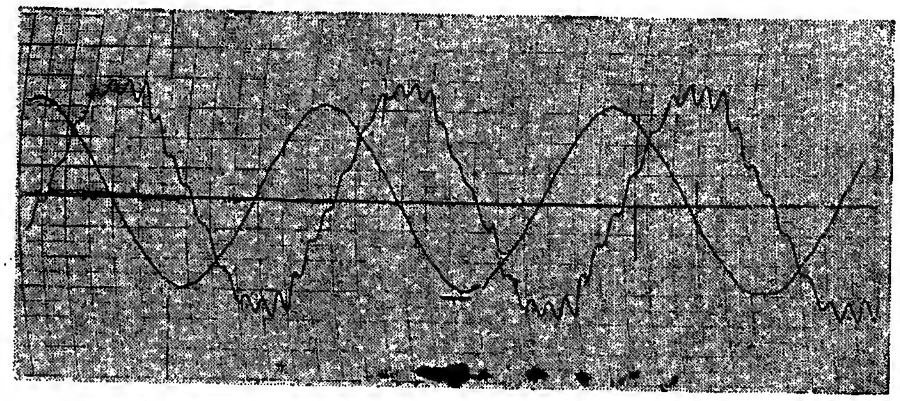

Figure 1. Oscillogram taken in London in 1908 on Ondographe Hospitalier.

This instrument represents an intermediate stage in harmonic analysis, coming as it does between the point-by-point plotting method and the modern reflecting and cathode-ray oscillographs. It was in reality a direct mechanical means of obtaining quickly a trace of the wave form by an automatic point by point record.

In Figure 1 the wave with the very pronounced harmonics is the voltage wave. The almost pure sine wave is the current wave. Time moves from right to left on the chart. These waves were produced from the power supplied to the school by the electricity-supply company operating in that area.

By comparing this voltage wave with one produced by any modern generator, one can readily appreciate the improvement that has been made in generator design, and, therefore, what we owe to the science of harmonic analysis in this field. The year in which the generator which supplied these waves was built is not known to the writer, beyond the fact that it was at some time in the eighteen nineties.

Further, an examination of the general shape of the voltage wave explains why the controversy raged over the so-called "sine-wave assumption." Possibly, when considering the machines in use in the early days, the opponents of the assumption were right. However, one would hardly care to take such a stand today when considering our modern machines. It will also be noticed that if the current wave be corrected for radial distortion it has a more sloping front and a steeper back than a pure sine wave.

Today we are in the habit of considering apparatuses with magnetic cores as producers of harmonics. The current wave was taken from a current passing through an almost pure reactance, as can be seen by the phase angle shift. A comparison of the harmonics appearing in the voltage wave and the current wave would indicate that when the harmonics of a voltage impressed on a circuit exceed a certain magnitude with respect to the fundamental wave, apparatuses with magnetic cores act as chokes or filters for harmonics in the current.

Such wave forms if put out by generators today would certainly cause untold trouble on communication circuits. It so happens that the gentleman who for a time was chief engineer of the telephone company operating in the area which was served by this system was the father of the writer of this discussion. Many a time the father has told his son of the terrible troubles he had with electric-power interference on his system, especially in the days when he was still struggling to try to operate single metallic ground-return telephone circuits.

The writer fully appreciates the great service rendered by the author of the paper to all those seriously interested in the subject of a-c wave form by producing this paper and can only hope that others, with equal knowledge and background in their respective branches of electrical-engineering science as the author has in his, will render the profession equal services by preparing papers of comparable scope and quality. As he says in his concluding sentence, the author has not attempted to tell us the whole story. He has, however, given us references which must prove to be invaluable. Those published from 30 to 50 years ago might otherwise have been in danger of dropping out of sight altogether.

Charles F. Scott (Yale University, New Haven, Conn.): To the significant history which Dr. Bedell recounts he himself has been a notable contributor, as is attested by the 12 references to his own work in the bibliography. To the story of the 1890 period I am able to add a few items relating to the Telluride power transmission and to the determination of wave form. Some of my own work and also that of Lamme and of Mershon are involved.

The wave form of the early commercial alternator with surface winding on a drum armature approximated the sine wave. The first Westinghouse toothed armature (one T-shaped tooth per field pole) produced a wave which caused less transformer-iron loss than that of the smooth armature. I undertook to measure the new wave form—the first such measurement at

the Westinghouse factory. I used the contact method but discarded the ordinarily used condenser and ballistic galvanometer and made direct readings by a Cardew (hot-wire) voltmeter. The instrument required normally about a quarter of an ampere for a fair deflection; it took enormously more when there was one contact per revolution of a 12-inch disk, as evidenced by a long soft arc. But the resulting curve was very definite; there was a flat zero for about five per cent of the half cycle and a double peaked maximum with a depressed *V* between the peaks, and the sides were fairly straight lines. The shape of the curve was responsive to the configuration of poles and teeth; thus, as the width of the tooth was greater than the pole, all of the field flux passed into the tooth through a slight angle, and the unchanging flux resulted in a prolonged "flat" zero in the curve. Lamme at once commented that he could change the wave form by reshaping the tooth.

One day Mr. Schmid said to me, "There are two new machines; test them and see what they will do." Then began my real education on synchronous operation; I varied motor field current from normal to zero and then did the same with the generator, observing effects on line voltage and current. I loaded the motor (about 40 horsepower) and made other tests. A few months later, about September 1, 1890, Mr. Schmid said that a 100-horsepower transmission had been sold to L. L. Nunn at Telluride, and we would use two alternators like those made for the transmission from Willamette Falls to Portland, Oreg. My job was to specify the equipment to accompany the two alternators. And without precedent I proceeded to devise a method and apparatus for motor starting and loading, the method of excitation of generator and motor, also to decide upon switches and indicating instruments and prepare instructions for operating a new type of plant. The only justification for some of the complication involved is that it worked. Dr. Bedell quotes P. N. Nunn as saying that the generator and motor were "identical to assure identity of wave form." Possibly, but I never heard of it until Mr. Nunn's explanation 40 years later. The Willamette-Portland and the Telluride transmissions were described by me in the Institute's first paper on Long-Distance Transmission for Light and Power.[1]

R. D. Mershon graduated from Ohio State University in 1890. I attended the commencement, and he told me of his method of measuring wave form. A few months later he developed it at the Westinghouse works. He placed in series with a contact a telephone receiver which responded with vigorous clicks. He introduced a d-c electromotive force which he adjusted until the click was suppressed. The d-c voltage required to just equal the contact voltage was read on a voltmeter. A new brush setting was then made, and the corresponding electromotive force at this point in the alternating wave again read on the voltmeter. This simple and satisfactory method was soon superseded by the oscillograph. Mershon described it in the *Electrical World* (1892, page 425).

Lamme calculated the wave form of the initial Niagara 5,000-horsepower generator and then measured it in a very original way. These he describes in a 12-page paper on "Early Work on First 5,000-Horsepower Alternators," prepared in 1920 at request of E. D. Adams and published in his "Niagara Power."[2] Under "New Method of Design" Lamme relates that I had prepared and showed him an iron filings picture of the magnetic field between the armature and field poles of the machine, made with the aid of a full-sized template. He continues "I believed I could plot the flux conditions by calculation. . . . The plotted field form corresponded to the electromotive force wave for one armature conductor . . . . The wave of other conductors (was the same but) displaced by an amount corresponding to the displacement of the armature conductors themselves . . . . I combined them to get the electromotive force wave of the machine.

"When the machine was set up for test, I arranged to wind a small wire cable around the external cylindrical field frame (about 12 feet in diameter), one end of this cable being attached to a small windlass, which was to be turned at a slow uniform rate to rotate the machine very slowly. The field was magnetized, and a d-c voltmeter was connected across the terminals of the armature winding with a view to taking direct readings at uniform intervals of time during the rotation. If the rotation were slow enough, the voltmeter needle would indicate in succession all the points in the electromotive force wave . . . . The measured wave coincided almost exactly with the predetermined calculation.

"Taking this as a basis, I worked on the method of design during my evenings for the next two or three years . . . . This developed method is the basis of the company's calculation system of today."

Dr. Bedell makes brief reference to William Stanley's pioneer work on the transformer. This is more fully described by Chesney and Scott as part of the Great Barrington demonstration.[3]

F. Bedell: We are indebted to Mr. Shill for bringing out several interesting points in his discussion. He has emphasized the troubles encountered on early telephone lines because of electric-power interference and has given us a good description of the Hospitalier Ondographe. The curves he has shown well illustrate the great irregularities that existed in the wave forms of early machines, to which attention has been called in the paper. Furthermore, his curves are evidence of the perfection attained in the delineation of wave forms by means of point-to-point curve tracers, which were highly developed and serviceable in their day but were soon outmoded on account of the inconvenience, as well as limited frequency range, of synchronous apparatus.

Irregularities even greater than those shown in these curves were frequently found in early machines. The increase in size of machines, with better design and standardization, has given us wave forms on power systems with remarkably small deviation from a true sine wave, conforming closely to our increasingly rigid standardization rules. One would hardly like to take a stand against the so-called sine assumption today, as Mr. Shill points out.

In the sine-wave assumption, however, it should be kept in mind that it is not assumed necessarily that current and electromotive forces are sine waves. It is assumed that they may be replaced by *equivalent* sine waves having the same rms values, displaced in phase so as to have the same power factor. The vector and circle diagrams based on this assumption have proved their usefulness for fifty years, even with wave forms departing widely from a sine wave. The proof of the pudding is in the eating.

It was early found that certain vector methods (as used, for example, in the once important three-voltmeter and three-ammeter methods for measuring power) were absolutely independent of wave form. It was further found that other methods with which we are all familiar, for example, the determination of performance characteristics by circle diagrams, gave results with engineering accuracy often better in fact than could be obtained by any other method, even though theoretically not free from error.

Such uses of vector and circle diagrams, employed in practically all our engineering projects, are too familiar to need elaboration, but let us take a particular example. In the predetermination of the regulation of a transformer from open-circuit and short-circuit tests, derived by vector methods based on the sine-wave assumption, the regulation is determined *more accurately* than it can be directly measured by commercial instruments. And this, too, in spite of the fact that the primary current of a transformer on open circuit is distorted necessarily, as we well know, by the effects of hysteresis!

An explanation of the fact that irregularities in wave form introduce such small error in vector diagrams based on the sine assumption may be found in the fact that, if fundamental quantities be represented by vectors in a plane, vectors representing harmonics would necessarily be at right angles thereto. This follows from the fact that no harmonic can have an inphase or power component with respect to the fundamental, for currents and voltages of different frequencies represent no power. Harmonics, compared with the fundamentals, are always small and, as the vectors by which they are represented are at right angles to the fundamental plane, their effect is still smaller and merely gives a slight distortion or warping to the plane-vector diagram by an amount too small to have significance. Studies in this direction will be found in reference 12 of the paper. The author has found the representation of alternating quantities by vectors in more than two dimensions useful in some special cases but not generally applicable without difficulty.

Although, as seen above, the validity of the sine-wave assumption and the usefulness of vector and circle diagrams based thereon do not depend upon having perfect or nearly perfect a-c wave forms, our efforts in standardization toward this end will be continued for engineering reasons, such as the effects upon insulation and communication, as discussed in the paper.

Some Air-Blast Circuit-Breaker Installations in Canada

Discussion and authors' closure of paper 42-157 by H. W. Haberl and R. A. Moore, presented at the AIEE Pacific Coast Convention, Vancouver, B. C., Canada, September 9–11, 1942, and published in AIEE TRANSACTIONS, 1942, December section, pages 859–63.

E. W. Knapp (Shawinigan Water and Power Company, Montreal, Que., Canada): It is today a well-established fact that automatic circuit breakers with high-speed and high rupturing-capacity characteristics are required for electric-power systems. The development of air-blast circuit breakers offers considerable promise of adequately meeting these requirements in the future. During the past few years the Shawinigan Water and Power Company has assisted in this development in Canada by utilizing their power system for primary tests during the development period. These tests brought out certain defects and limitations, and, as a result, improvements have been effected. However, it is expected that this equipment will be subject to the usual "growing pains" but will improve with "time and experience." Operating experience to date has also revealed a number of weaknesses, and, in general, the necessary remedial measures have been taken, particularly in those cases where the cause of failure has been established definitely. Normal operating speeds are quite fast, and this feature should prove of considerable value, particularly on power-system networks where transient stability or power-arc damage present problems. It should be noted, however, that although the 69-kv design has been tested to 100 per cent of rated rupturing capacity, the 220-kv design has not been fully tested above 40 per cent of rated rupturing capacity.

Automatic reclosing of power circuits, following transient faults, is playing an important role in power-service improvements. It is quite probable that in the near future, this feature will be considered as an integral part of any system plan, along with relay protections and control. This feature may also be supplemented in special cases with single-phase switching. The air-blast circuit-breaker would appear to be ideally suited to this method of operation, caused by inherently high operating speeds. The authors have attempted to explain briefly a means of adapting the circuit breaker under consideration to automatic reclosing, but I do not fully understand the explanation. It is assumed that "extremely fast reclosing" means 0.35 second or less total time. In this particular design it is not possible to reclose the interrupter contacts while maintaining a high pressure in the arcing chamber. This tends to increase the possibility of restrike across the interrupter contacts, unless the isolator switch is at least partially open before the air blast is stopped. The necessity of operating the isolating switch might result in considerable delay in the automatic reclosing operation, unless the control arrangement is revised. Further explanation of the scheme, together with operating times should prove of interest.

L. B. Chubbuck: For discussion, see item elsewhere on this page.

H. W. Haberl and R. A. Moore: The authors of this paper gratefully acknowledge the interest shown by power-company engineers and especially those who have presented written discussions. A number of interesting points have been brought out by the discussers which we believe should be clarified. As most of the discussion is along parallel lines, our closing remarks will be directed toward the discussion as a whole.

Certain tests reported are referred to as "synthetic tests." They are obviously not synthetic tests. Synthetic means artificial. The word "synthetic" has been applied to the method used by large manufacturing companies to test circuit breakers beyond the short-circuit capacity of the available generating system. In the tests reported by the authors, the kilovolt-amperes interrupted by the breaker were, in every case, identically the same kilovolt-amperes which flowed into the fault from the line and generating system. In other words, the system was carrying a load of several hundred thousand kilowatts, just before, during, and just after the short circuit interrupted by the breaker, the conditions being the same as when a breaker clears a fault in service. There was obviously nothing "synthetic" about such tests.

Perhaps the intention was merely to question how much more interrupting capacity the 230-kv breaker has in excess of 1,000,000 kva interrupted in the tests at 230 kv. The author's paper reports other tests on the single element of the 230-kv breaker interrupting over 5,000 amperes at about 60 kv (phase-to-phase across a 60-kv line carrying full load), such interruption being somewhat over 300,000 kva on the single element. The 230-kv breaker has six of these elements in series per pole, making 18 elements in the three-pole breaker. Multiplying 300,000 by 18 gives 5,400,000 kva. The authors consider these tests to prove adequately that the 230-kv breaker has an interrupting capacity in excess of its rating of 2,500,000 kva.

Pistons and cylinders are mentioned by the discussers as possible sources of trouble in air-blast breakers. Pistons and cylinders operated by compressed air were applied to brakes on railway trains many years ago (by the Westinghouse company). Air brakes are very dependable.

One discusser refers to the noise of air-blast breakers and is concerned about its effect on the nerves of operators. A 230-kv air-blast breaker opening a short circuit makes a noise about like the exhaust of a standard steam locomotive starting a heavy train, which does not appear to bother the crew working within 40 feet of the blast. The operator in a station works at a control board usually 100 feet or more away from the breakers and within enclosing walls. He is not at all disturbed.

The discussers refer to high-speed reclosing in the high-voltage classes of breakers described. The 138-kv breaker will reclose in 20 cycles and the 230-kv breaker in 25 cycles. This timing can be decreased if a specific application warrants. However, the authors feel that if the breaker reclosing time was decreased to less than 15 cycles, additional delay in the form of control would need to be added, as the arc products on transmission-line faults are not blown away in less than that time, and on single-phase switching the arc on the de-energized phase has been known to be maintained for an appreciable time by the induced voltage produced from the sound phases.

To obtain successive shots in air-blast breakers it is only necessary to add storage capacity. Most types of the air-blast breakers described have three operations stored in their individual tanks, and with the aid of storage capacity this number of operations can be increased at will. The moving parts of certain of these air-blast breakers in the extreme high-voltage class are very accessible, and contact inspection on the 230-kv air-blast breakers can be made within 20 minutes. Comparing this with a 230-kv oil-breaker contact inspection time which takes hours, we believe the advantages are in favor of the air breaker.

High-voltage air-blast breakers can be safely mounted indoors where a large quantity of stored inflammable material is a potential fire hazard; this indeed is an advantage for the air-blast breakers.

The arcing time of the air-blast breaker is independent of the magnitude or phase angle of the currents involved. This is indeed an advantage over the modern oil breaker where clearing times in the neighborhood of six cycles can be obtained where the current is of sufficient magnitude to have the deionization or the explosion principle applied. However, on small currents of low power factor such as the charging current of transmission lines the air-blast-breaker arcing time is the same as with the heavy currents. The modern oil breaker under charging current conditions has been known to fail to interrupt where the magnitude of the current is less than the amount required for the explosion or deionization principle to apply.

Design and Operation of High-Voltage Axial Air-Blast Circuit Breakers

Discussion and author's closure of paper 42-155 by Armin K. Leuthold, presented at the AIEE Pacific Coast convention, Vancouver, B. C., Canada, September 9–11, 1942, and published in AIEE TRANSACTIONS, 1942, December section, pages 869–75.

L. B. Chubbuck (Canadian Westinghouse Company, Ltd., Hamilton, Ont., Canada): As the organization with which the writer is connected manufactures both air-blast and oil breakers, the writer feels free to offer a few comments on both types.

Low-voltage air-blast breakers are definitely free of oil hazard, though the high-voltage breakers usually include oil-immersed current transformers in large fragile porcelains.

While failures have occurred in the past with oil circuit breakers, modern oil breakers fully tested and used within their rating have an excellent record under heavy everyday service. Their arc-rupturing devices are very effective, and all interruption

occurs quietly within heavy grounded metal tanks. Modern high-voltage and low-voltage oil breakers are very compact, a 15-kv, 1,000,000-kva metal-clad structure running a little over 36 inch centers.

Air-blast breakers have also had their failures. This type of breaker has short *arcing* time, though any longer time extending until the series disconnecting switch opens would be serious. The *over-all* opening time (the important feature) averages a little less than for commercial oil breakers but can be met by high-speed oil breakers.

The opening of an air-blast breaker is accompanied by considerable noise and flame, rather nerve-racking to an adjacent operator.

Because of limited air supply, an air breaker may be safely operated only two or three times successively. The operating high-pressure piping, valves, relays, and cylinders are rather an involved precision equipment and require high-grade maintenance, particularly for outdoor service. Some of these moving parts are rather inaccessible, enclosed in high porcelains. At Arvida the 154-kv breakers are mounted *indoor*.

We note that, because of lack of suitable high-power laboratories, the authors can provide only "synthetic" test proof of their larger ratings, based on a few system tests. We do not consider such data conclusive. During the development of our air-blast breakers, thousands of tests were made on all parts, and complete poles, to full rating, and overvoltage, in a laboratory of ample capacity.

In conclusion, the authors have given us two very interesting and instructive papers covering the development of this new equipment in Canada.

A. K. Leuthold: High-voltage air-blast circuit breakers can be equipped either with, or without, oil-immersed current transformers, but even in the former case, which is often preferred from the economical standpoint, the oil hazard, compared to an oil circuit breaker, is very small, because no arc interruption has to be carried out under oil.

The low-voltage air-blast breakers are also very compact in design. For example: seven-kilovolt breakers require a space from center to center of approximately 34 inches and 13-kv breakers of approximately 42 inches.

Neither with our outdoor nor our indoor type of air-blast circuit breakers can flames be noticed at the breaker exhaust openings. The noise from an air-blast breaker erected outdoors is not objectionably loud, while the noise from a breaker erected indoors is similar to that of a modern high-speed d-c breaker when interrupting a heavy short circuit.

Breakers equipped with automatic reclosing devices can open, reclose, and open a second time in less than 20 cycles without requiring refilling from the main air-storage tank. After two breaker opening operations, automatic refilling takes place from the main storage tank in approximately four to six seconds, and further switching operations can then be carried out.

Experience has shown that the various pistons, applied for the fully automatic operation of the breaker, operate very satisfactorily, even under very low temperature. On outdoor breakers, this piston assembly is carefully protected against snow and rain and, if desired, can be kept above freezing point by means of small heaters similar to those applied on the motor-control pedestals of outdoor oil circuit breakers.

The arcing chambers of high-voltage breakers are designed with inspection openings or other devices, which enable the movable arcing contacts to be inspected, or even replaced if necessary, in a few minutes. At Arvida, the 150-kv air-blast circuit breakers are installed indoors, because they had to replace two oil circuit breakers previously erected in the same building where two 75,000-kva transformer banks are located. This customer preferred to eliminate the oil hazard by applying two air-blast circuit breakers in place of the previous oil circuit breakers.

The high-voltage air-blast circuit breakers equipped with potential-controlled multiple arc breaks, are tested in our large breaker test plant by breaking the partial interrupting capacity with one arc break only, which enables one to judge what the performance of this breaker will be under full-rated interrupting capacity. A definite conclusion can be drawn from these tests because the voltage distribution between the individual arc breaks is equal on account of the potential control of the arc breaks, which is achieved by means of small capacities.

Through a series of developments, the manufacturer has achieved a very high performance from the high-voltage air-blast circuit breakers which, besides the short interrupting time, enables automatic single- or three-phase high-speed reclosure to be carried out.

This insight into the latest breaker developments, including testing and operating experiences, should induce and encourage power companies to collect experience on their own networks by applying this new type of circuit breaker in order to gain valuable operating data for further improvement in the protection and stability of their high-voltage transmission lines and power-distribution systems.

Design, Manufacture, and Installation of 120-Kv Oil-Filled Cables in Canada

Discussion and authors' closure of paper 42-148 by D. M. Farnham and O. W. Titus, presented at the AIEE Pacific Coast convention, Vancouver, B. C., Canada, September 9–11, 1942, and published in AIEE TRANSACTIONS, 1942, December section, pages 881–8.

A. H. Frampton (The Hydro-Electric Power Commission of Ontario, Toronto, Ont., Canada): Under the heading "System," section 2, the authors state that cable connections were used between the step-down transformer terminals and the station bus "as providing a substantial saving in steel structure, greater compactness, and better appearance, and much less exposed high-voltage circuit." In the apparently restricted space available at the site of station *B*, the value of the second and fourth points may be granted. However, it is difficult to accept the inference that the saving of the cost of the additional structures required to accommodate open connections to the transformers had a controlling influence in the decision to use cable at this point. The acceptance of this inference is made more difficult by the assumptions that may be drawn from the statements under "System," section 3, that the line route had to be shortened to approximately one third, and the acquisition of expensive right of way avoided in order to justify the main cable section as against the alternative overhead construction.

It would be interesting if the authors could expand on these points. Perhaps they would be prepared to suggest a rule-of-thumb figure as representing the approximate value of right-of-way saving necessary to justify the adoption of cable constuction.

From Figure 2 of the paper it is presumed that this cable system operates in parallel with 60-kv overhead circuits. From the discussion, it is inferred that varying amounts of power are required to be transmitted between stations *A* and *C*, in order to maintain the most efficient loading on certain generating sources. As these parallel paths would obviously have different impedance characteristics, it would appear that the maintenance of a proper subdivision of load between the parallel paths would occasion difficulties. It would be of interest to know whether any special operating or other procedures have been established in this connection.

Herman Halperin (Commonwealth Edison Company, Chicago, Ill.): The authors are to be complimented for the thoroughness of their past investigations of design and installation details and of their present investigations of operating matters. If, as in this case, engineers devote some time and efforts to the study of all details, problems relating to oil-filled cable systems become simple.

Records of duct temperatures, and so forth, as they are planned, should be of considerable value in obtaining the maximum allowable load rating for the cable in the actual installation. As load ratings are most important, it would be of interest to have more detailed information given on the methods being used by the authors and on any special points relating to loading.

According to Table I of the paper, 70 degrees centigrade is considered the maximum allowable copper temperature in accordance with the Association of Edison Illuminating Companies specifications. As indicated in my recent AIEE paper on "Load Ratings of Cable—II,"[1] such cable could be operated safely at higher temperatures. If this is attempted, one, of course, must watch out for limitations, such as reservoir capacity or induced sheath potentials.

The Canadian-developed reservoirs shown in Figure 6 of the paper are of interest. The arrangement may be less expensive than those used in the United States. What material is used for the cell walls?

The design of the conductor with flat strands reduces considerably the free oil space between conductor and paper as compared with conductor with ordinary round strands. Have any test data or calculations

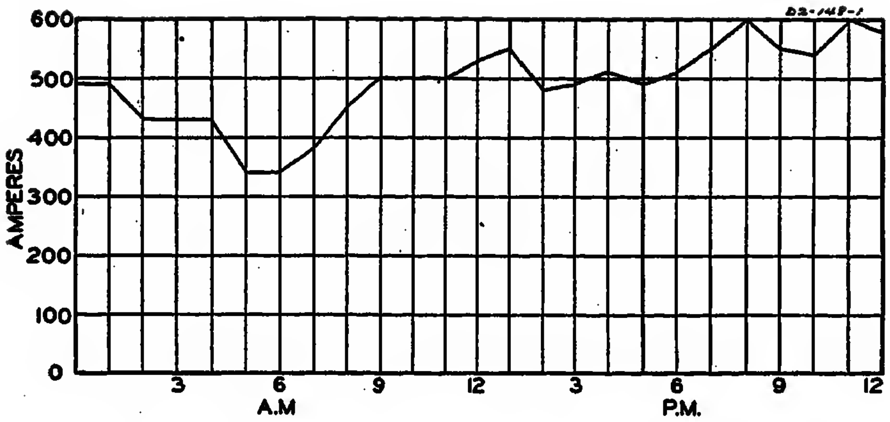

Figure 1. Typical daily load curve for 120-kv cable

Sheath currents not flowing. T_0=20 degrees centigrade

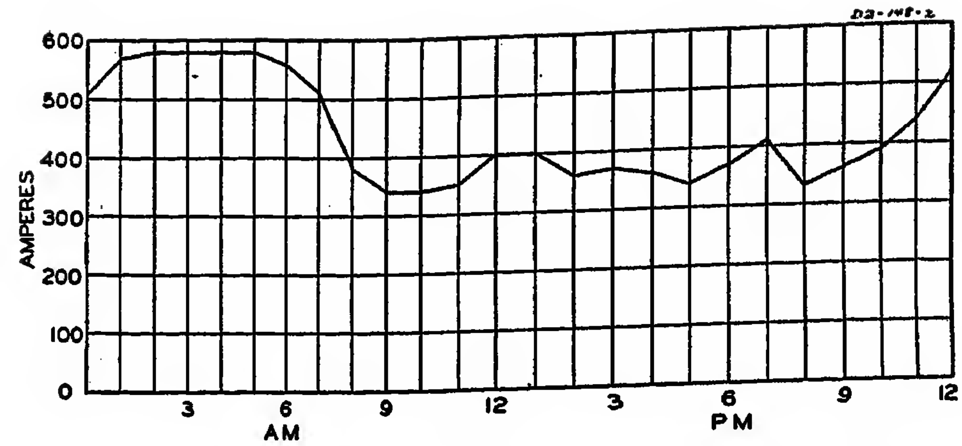

Figure 2. Typical daily load curve for 120-kv cable

Sheath currents flowing. T_0=10 degrees centigrade

been made on the relation of the maximum stresses for these two types of conductors?

The average coefficients of friction of 0.25 to 0.30 for pulling cable into the ducts are less than usually obtained. We have found higher values in pulling cables into precast-concrete round ducts, using a heavy grease on the cable. While the grease is not a very good lubricant, as demonstrated by our tests, it is used mainly to retard or prevent corrosion of the sheath. It seems to me that the main considerations in determining maximum allowable pulling strains are possible harmful effects on the conductor, on the rest of the material inside the sheath, and on the outer surface of the sheath.

In general, the methods and carefulness used on the whole project described in the paper were apparently of such a nature as to permit high allowable loading and still obtain a satisfactory operating record over a period of decades.

1. LOAD RATINGS OF CABLE—II, Herman Halperin. AIEE TRANSACTIONS, volume 61, 1942, pages 930–42.

D. M. Farnham and O. W. Titus: Mr. Frampton feels that the saving of steel alone would not be a controlling factor in the use of cable from the station bus to the transformer. All projects, of course, contain a number of elements of cost. The sum total of all elements is the determinant. In this instance steel was one substantial element. This was in some measure due to the shape of the premises which made it desirable, even necessary, to place the high-voltage outdoor structure along the south side of the property from east to west, using the entire width. It was, therefore, necessary to place the four transformer banks in a row running from east to west and north of the high-voltage structure. The steelwork required to feed these transformers by overhead construction, plus the cost of the overhead construction, was estimated to be higher than the cost of the oil-filled cables. Part of this advantage may have resulted from a reasonable cable-installation cost, since other oil-filled cables and equipment were being installed at the time in the immediate vicinity. Appearance and "dead-front" characteristics might also be appraised as contributing factors if that were necessary.

Our opinion is that for short runs, as encountered in this case, the problem is worth investigating thoroughly before a decision is reached to use either the overhead or underground method.

As underground costs vary differently from those for overhead with difference in load and raw-material costs, we would not care to set up even an approximate rule-of-thumb figure such as Mr. Frampton suggests, particularly at times such as these.

Mr. Frampton's question as to how the present 60-kv ring system is made to carry its share of load when its impedance is so much greater than that of the cable is well taken.

This difficulty was very cheaply and effectively overcome by splitting the high-voltage bus at station *C* and connecting the cable to one pair of overhead lines and the ring to the other pair. These pairs of lines were paralleled approximately 90 miles away.

Table I. Maximum Allowable Current (Amperes)

Cable (Thousands of Circular Mils)	Allowable Copper Temperature (Degrees Centigrade)	Cables in Duct Bank	Sheath Currents Flowing	Sheath Currents Not Flowing	Ground Temperature (Degrees Centigrade) 20	15	10	5
300	70	3	X		382	403	422	442
300	70	3		X	412	434	450	476
300	70	6	X		348	368	387	405
300	70	6		X	372	393	413	432
300	80	6	X		380	398	415	431
650	70	3	X		528	558	585	612
650	80	3	X		576	602	627	652
650	70	3		X	635	670	703	736
650	80	3		X	693	724	754	783

Figure 3

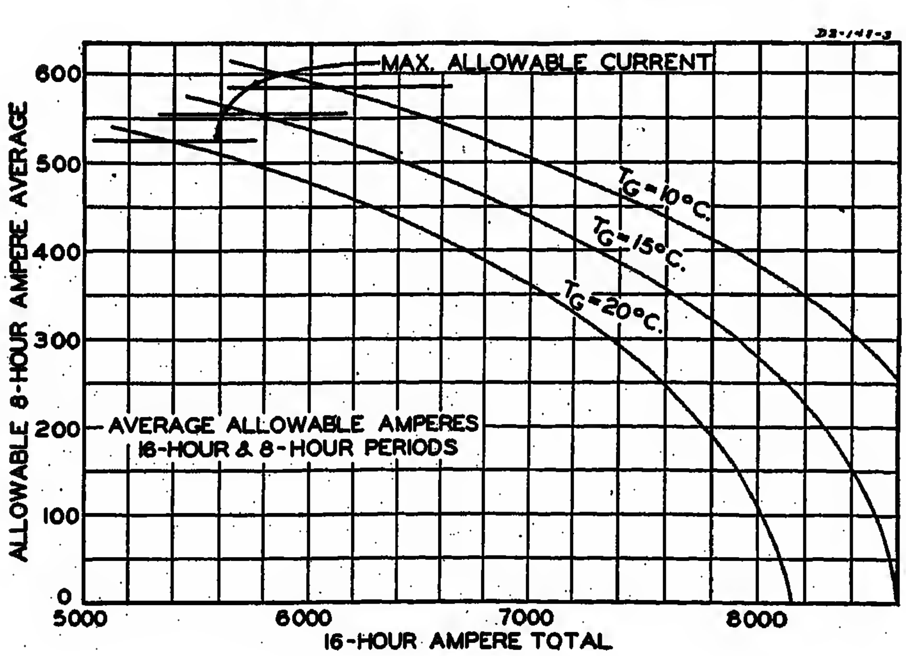

Figure 4

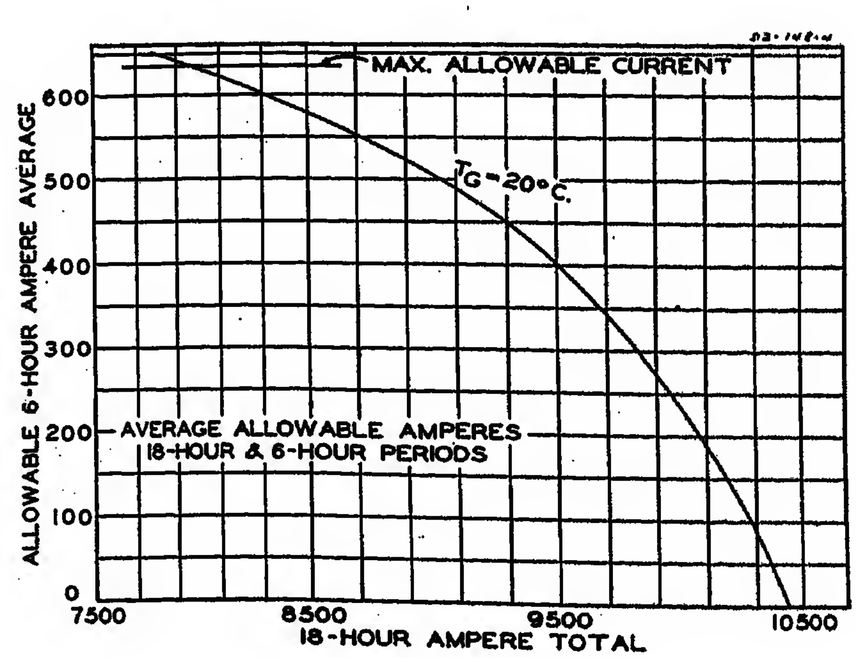

The combined impedances were such that the load divided correctly to take full advantage of both tie circuits.

The authors are grateful for Mr. Halperin's kind remarks. The Canadian reservoirs employed plain steel diaphragms, principally because of wartime difficulty in securing stainless steel within the time permissible.

No tests or calculations were made on the maximum dielectric stresses for the shaped conductors as compared with conventional stranding.

During the development of the pulling eyes, tension tests were made on conductors, paper-wrapped but without the lead sheath. These tests determined both the effectiveness of the pulling eye and the maximum tension on the conductor permissible without permanent deformation. In the field, pulling tensions were kept below these values in all cases. Any added strength caused by the lead sheath was regarded only as added factor of safety.

In replying to the second paragraph of Mr. Halperin's discussion, the listed calculations are samples of those used in establishing the loading schedule of the cables:

Allowable peak load $=I$ at loss factor stated

Loss factor (by design) $=62^1/_2$ per cent $=\dfrac{(I\,\text{avg})^2R}{I^2R}$

Daily basis 100 per cent loss $=I^2\times R\times 24$

$62^1/_2$ per cent loss factor $=$

$$\frac{\text{avg}\,(I^2)\times R\times 24}{I^2\times R\times 24}=0.625$$

or $\dfrac{\text{avg}\,(I^2)}{I^2}=0.625$

or avg $(I^2)=0.625I^2$

For any period of the day

Let

$Ix^2=\text{avg}\,(I^2)$

and

$Ix^2=\text{avg}\,(I^2)$ for the remainder of the 24 hours

Then

$$(Ix^2\times X\text{ hours})+(Iy^2\times Y\text{ hours})=0.625I^2\times 24$$

or

$$I^2y=\frac{(0.625\times I^2\times 24)-XIx^2}{Y}$$

$$=0.625\times I^2\times\frac{24}{y}-\frac{x}{y}Ix^2$$

Take X as 18 hours and y as 6 hours then

$I_6=\sqrt{(0.625\times I^2\times 4-3I_{18}^2)}$

(a). Sheath currents flowing, $T_G=20$ degrees centigrade. $T_c=70$ degrees centigrade $-I=528$.

(b). Sheath currents not flowing $T_G=20$ degrees centigrade. $T_c=70$ degrees centigrade $-I=635$.

(For allowable maximum loading see Table I of this discussion.)

For (a) $I_6=\sqrt{(0.625\times 528^2\times 4-3I_{18}^2)}=\sqrt{3(232,\,320-I_{18}^2)}$. For (b) $I_6=\sqrt{(0.625\times 635^2\times 4-3I_{18}^2)}=\sqrt{3(336,\,021-I_{18}^2)}$.

Curves in Figures 1, 2, 3, and 4 of this discussion are made on the basis of these or similar calculations.

This allows cable loadings to a maximum for 18 hours each day, and from these total amperes a load rating can be had for the succeeding six hours, with a resultant loss factor of $62^1/_2$ per cent (see typical loading curves herewith).

This method of scheduling the loading has been used since the cables went into service, with careful attention being paid to temperatures and duct-mouth movements. The idle duct (that is a duct adjacent to a loaded duct) temperature at various locations has been recorded and shows a variation of from $38^1/_2$ degrees centigrade to $40^1/_2$ degrees centigrade, which would indicate a fairly constant copper temperature.

Duct-mouth movements have been recorded both daily and weekly. The daily movements are in the nature of one eighth of an inch or less, while the weekly movement is in the order of three eighths of an inch. Outages or long periods of light loads increase these movements considerably.

The flow of oil to and from reservoirs has been recorded, the daily or even weekly quantity has been approximately one gallon per phase per section, this of course is divided on the two ends. The seasonal variation has so far been only a transfer from cables to reservoirs and has amounted to about 13 gallons per phase per section. This quantity would have to be corrected for the temperature change of the reservoir immersion oil amounting to 0.085 gallon per degree centigrade. The temperature change has been 45 degrees centigrade which is equivalent to 3.8 gallons; thus the actual oil expelled because of seasonal change has been about $9^1/_2$ gallons per phase per section.

Up to the present sufficient power has been handled by using a maximum copper temperature of 70 degrees centigrade. However, if the need arose, there would be little hesitation in increasing this limit to 80 degrees centigrade or even higher. We are now confident that oil demands would not be excessive for the present reservoirs even at extreme temperatures.

13. Circuit Breaker for the Home, Frank Thornton, Jr., O. S. Jennings. *Electric Journal*, volume 28, February 1931, pages 117–19; also "Enter—a New Domestic Circuit Breaker," Frank Thornton, Jr., *Electrical World*, volume 97, February 7, 1931, pages 287–9.

14. Further Development of the Compressed-Air Breaker (in German), O. Mayr. Verband Deutscher Elektrotechniker *Fachberichte* (Berlin), 1931, pages 45–7.

15. Interrupting Performance of Air Circuit Breaker, G. G. Grissinger. *Electric Journal*, volume 28, August 1931, pages 464–5.

16. Latest Developments in Compressed-Gas Circuit Breaker Design, O. Mayr. *AEG Progress* (Berlin), volume 7, January-February 1931, pages 30–2.

17. Newer Development of the High-Speed Breaker for Heavy Current Values and High Interrupting Speeds (in German), A. Cohn. Verband Deutscher Elektrotechniker *Fachberichte* (Berlin), 1931, pages 157–8.

1932

18. Characteristics of the High-Speed Circuit Breakers for the Lackawanna Suburban Electrification, M. D. Henshaw. *General Electric Review*, volume 35, March 1932, pages 154–62.

19. High-Power Circuit Breakers Without Oil (in German), O. Mayr. *Elektrotechnische Zeitschrift* (Berlin), volume 53, January 28, 1932, pages 75–81; February 11, 1932, pages 121–3.

20. Results of Recent Investigations of the Interrupting Phenomena in Alternating-Current Arcs (in German), data collected by F. G. Ruegg, J. Kopeliowitsch, J. Biermanns, Association Suisse des Electriciens *Bulletin* (Zurich), volume 23, October 28, 1932, pages 565–92; data collected by O. Mayr, A. Roth, F. Kesselring, November 11, 1932, pages 605–29.

21. Testing of Low-Voltage Network Protectors, F. D. Johnson. *Electric Journal*, volume 29, August 1932, pages 375–6.

1933

22. Arc-Rupturing Device Takes Novel Forms. *Electrical World*, volume 102, November 4, 1933, page 601.

23. Circuit Breaker Protection for Industrial Circuits, H. J. Lingal, O. S. Jennings. AIEE Transactions, volume 52, 1933, pages 568–76.

24. Compression-Type Low-Voltage Air Circuit Breaker, D. C. Prince. AIEE Transactions, volume 52, 1933, pages 844–7.

25. De-Ion Circuit Breakers for Steel-Mill Service, R. C. Dickinson. *Electric Journal*, volume 30, October 1933, pages 415–17.

26. Development of Practical Compressed-Air Breakers (in German), W. Uebermuth. Verein Deutscher Ingenieure *Zeitschrift* (Berlin), volume 77, January 14, 1933, pages 40–4.

27. Further Development of Low-Pressure Air Breakers (in German), A. Roth. *Electrotechnik und Maschinenbau* (Vienna), volume 51, April 2, 1933, pages 184–9.

28. 220-Kv Air-Blast Breaker Rated 1,500,000 Kva. *Electrical World*, volume 102, November 4, 1933, page 580.

1934

29. Air-Blast Circuit Breaker. *Electrical Times* (London), volume 86, November 8, 1934, pages 585–7.

30. Air-Break Sectionalizing Switches for Ring Primary, C. A. Mathews. *Electrical World*, volume 103, January 27, 1934, pages 146–7.

31. Circuit Breaker for Radio Speech-Control Circuits, R. W. Bauer, J. W. Seaman. *General Electric Review*, volume 37, November 1934, pages 495–7.

32. Circuit Protection in Industrial Plants, W. C. Ford. *Electric Journal*, volume 31, September 1934, pages 374–5.

This bibliography on circuit-interrupting devices was prepared under the sponsorship of the AIEE committee on protective devices. The items are divided into sections according to subject matter. In each section the entries are numbered consecutively, subdivided chronologically beginning with 1928, and arranged alphabetically by title under each year, the first significant word of the title determining the alphabetical position. This bibliography was published in pamphlet form by the AIEE during 1942.

33. Complete Range of Air-Blast Breakers. *AEG Progress* (Berlin), number 2, 1934, pages 24–5.

34. High-Power Circuit Breakers Without Oil (in German), **O. Mayr.** *Elektrotechnische Zeitschrift* (Berlin), volume 55, August 2, 1934, pages 757–60; August 9, 1934, pages 791–4; August 23, 1934, pages 837–40.

35. Special Application of the Principles of Flow in Oilless Circuit Breakers (in German), **L. Haag, O. Schwenk.** *Electrotechnische Zeitschrift* (Berlin), volume 55, March 1, 1934, pages 211–13.

1935

36. Brown Boveri Air-Blast High-Speed Circuit Breaker, **W. Walty.** *Brown Boveri Review* (Baden), volume 22, November 1935, pages 199–207.

37. Development of a Compressed-Air Breaker (in German), **H. Thommen.** Association Suisse des Electriciens *Bulletin* (Zurich), volume 26, October 11, 1935, pages 590–5.

1936

38. Switching Problems in High Voltages (in German), **F. Kesselring, F. Koppelmann.** *Archiv fuer Elektrotechnik* (Berlin), volume 30, February 18, 1936, pages 71–108.

1937

39. Further Development of the Compressed-Air Breaker With Double-Acting Air Flow (in German), **O. Schwenk.** Verband Deutscher Elektrotechniker *Fachberichte* (Berlin), volume 9, 1937, pages 90–2.

40. Operation of Outdoor Circuit Breakers at Low Temperature, **E. V. Caton.** *Electrical News and Engineering* (Toronto), volume 46, July 1, 1937, pages 24–5.

1938

41. AEG Air-Blast Breaker. *AEG Progress* (Berlin), number 2, 1938, pages 25–31.

42. Compressorless Air-Blast Circuit Breaker (in German), **F. Petermichl.** *Elektrotechnik und Maschinenbau* (Vienna), volume 56, May 29, 1938, pages 286–9.

43. "De-Ion" Air Circuit Breakers for A-C Feeder, Motor Starting, and Station Auxiliary Service, **R. C. Dickinson.** AIEE Transactions, volume 57, 1938, November section, pages 649–53.

44. Enclosed Low-Voltage "De-Ion" Air Circuit Breaker of High Interrupting Capacity, **J. Sandin.** AIEE Transactions, volume 57, 1938, November section, pages 657–61.

45. Logan Auxiliaries Have 2,300-Volt Air Breakers, **P. Sporn.** *Electrical World*, volume 110, October 22, 1938, pages 30–2 (1154–6).

46. Operating Experience With Air-Blast Circuit Breakers, **B. K. Boulton.** *Electrical News and Engineering* (Toronto), volume 47, August 1, 1938, pages 20–2, 30.

47. Progress in the Construction of Compressed-Air Breakers (in German), **J. Biermanns.** *Elektrotechnische Zeitschrift* (Berlin), volume 59, February 17, 1938, pages 165–8; February 24, 1938, pages 194–7.

1939

48. Air-Blast Circuit Breakers for Wide Voltage Range, **C. W. Baker, R. A. Moore.** *Electrical News and Engineering* (Toronto), volume 48, November 15, 1939, pages 22–5.

49. Brown Boveri Air-Blast High-Speed Circuit Breaker and Its Importance for Protection of Networks, **R. M. Wild, J. Schneider.** *Brown Boveri Review* (Baden), volume 26, April-May, 1939, pages 106–11.

50. Further Development of Air-Blast High-Speed Circuit Breaker up to Highest Voltages Encountered in Service and for Outdoor Erection, **H. Tommen.** *Brown Boveri Review* (Baden), volume 26, March 1939, pages 55–68.

51. High-Power "De-Ion" Air Circuit Breaker for Central-Station Service, **R. C. Dickinson.** AIEE Transactions, volume 58, 1939, August section, pages 421–5.

52. New Air Breaker Has Novel Chute Design, **L. S. Hobson.** *Electrical World*, volume 112, October 7, 1939, page 76 (1052).

53. New High-Capacity Air Breaker, **L. R. Ludwig, G. G. Grissinger.** AIEE Transactions, volume 58, 1939, August section, pages 414–18.

54. Typical European High-Speed Air-Blast Circuit Breaker, **W. S. Edsal.** *Allis-Chalmers Electrical Review*, volume 4, December 1939, pages 5–9.

1940

55. Air-Blast Breakers Gain Acceptance. *Electric Light and Power*, volume 18, April 1940, pages 48–58.

56. Air-Break Equipments. *Electrical West*, volume 85, September 1940, pages 45–7.

57. Air Circuit Breakers for Resistance-Welding Machines, **Wayman A. Holland.** *Welding Journal*, volume 19, January 1940, pages 41–2.

58. Circuit Interruption by Air Blast, **W. S. Edsall, S. R. Stubbs.** AIEE Transactions, volume 59, 1940, September section, pages 503–09.

59. Cross-Air-Blast Circuit Breaker, **D. C. Prince, J. A. Henley, W. K. Rankin.** AIEE Transactions, volume 59, 1940, September section, pages 510–17.

60. Design and Construction of High-Capacity Air-Blast Circuit Breakers, **H. E. Strang, A. C. Boisseau.** AIEE Transactions, volume 59, 1940, September section, pages 522–7.

61 Electrical Developments of 1939, **Guy Bartlett.** *General Electric Review*, volume 43, January 1940, pages 3–54. Switchgear, pages 11–14.

62. Experience With Air-Blast Circuit Breaker at Arvida, **A. Leuthold.** *Electrical News and Engineering* (Toronto), volume 49, September 15, 1940, pages 34–7.

63. "Magne Blast" Air Circuit Breaker for 5,000-Volt Service, **E. W. Boehne, L. J. Linde.** AIEE Transactions, volume 59, 1940, April section, pages 202–08.

64. Magnetic "De-Ion" Air Breaker for 2,500–5,000 Volts, **L. R. Ludwig, R. H. Nau.** AIEE Transactions, volume 59, 1940, September section, pages 518–22.

65. Modern Trends of Low-Voltage Air Circuit Breakers, **J. W. Seaman.** AIEE Transactions, volume 59, 1940, January section, pages 24–9.

66. New 15-Kv Pneumatic Circuit Interrupter, **L. R. Ludwig, H. L. Rawlins, B. P. Baker.** AIEE Transactions, volume 59, 1940, September section, pages 528–33.

67. Performance Justifies Selection of Air-Blast Breakers, **H. W. Haberl.** *Electrical World*, volume 114, September 21, 1940, pages 51, 121, 123 (841, 911, 913).

68. Recent Development in Compressed-Air Circuit Breakers. *Power Plant Engineering*, volume 44, September 1940, pages 78–82.

69. Relay and Circuit-Breaker Protection for D-C Machines, **H. Bany.** *General Electric Review*, volume 43, August 1940, pages 312–19.

Section B

Circuit Breakers—Oil

1928

1. High-Voltage Oil Circuit Breakers for Transmission Networks, R. Wilkins, E. A. Crellin. AIEE Transactions, volume 47, 1928, pages 148–56.

2. Improvements in Moderate-Capacity Oil Circuit Breakers, J. B. MacNeill. AIEE Transactions, volume 47, 1928, pages 793–7.

3. Interrupting-Capacity Testing of Large Oil Circuit Breakers, B. M. Jones, E. F. Zeigler. *Electric Light and Power*, volume 6, December 1928, pages 26–9, 107–09.

4. Operating Experience With High-Speed Oil Circuit Breakers, B. F. Bardo. AIEE Transactions, volume 47, 1928, pages 1293–6.

5. Present and Future Switchgear Practice, H. W. Clothier. *Electrical Engineer of Australia and New Zealand* (Melbourne), volume 4, February 15, 1928, pages 411–13.

6. Recent Research on Current Interruption Under Oil (in German), J. Kopeliowitsch. Schweizerischer Elektrotechnischer Vercin (Association Suisse des Electriciens) *Bulletin* (Zurich), volume 19, September 7, 1928, pages 541–77.

1929

7. Circuit Breakers for Changing Taps on Transformers, E. K. Read. *Power*, volume 69, January 8, 1929, page 59.

8. Introduction to Researches on Circuit Breaking, E. B. Wedmore, W. B. Whitney, C. E. R. Bruce. Institution of Electrical Engineers *Journal* (London), volume 67, May 1929, pages 557–78.

9. New Design Features in Oil Circuit Breakers, A. W. Hill. *Power*, volume 70, September 17, 1929, pages 444–5.

1930

10. Extinction of a Long A-C Arc, J. Slepian. AIEE Transactions, volume 49, 1930, pages 421–30.

11. Field Tests on De-Ion Grid Breakers, L. W. Dyer. *Electrical World*, volume 95, April 19, 1930, pages 786–92; April 26, 1930, pages 844–8.

12. High-Voltage Oil Circuit Breakers (book), R. Wilkins, E. A. Crellin. McGraw-Hill Book Company, New York, 1930.

13. Use of Oil in Arc Rupture With Special Reference to System Stability, B. P. Baker, H. M. Wilcox. AIEE Transactions, volume 49, 1930, pages 431–41.

1931

14. Arc Energy Liberation Fixes Breaker Pressures, W. M. Leeds. *Electrical World*, volume 98, December 26, 1931, pages 1138–41.

15. Circuit-Breaker Duty Affected by Circuit Characteristics, W. F. Skeats. *Electrical World*, volume 97, June 27, 1931, pages 1230–2.

16. Circuit-Breaker Field Tests on Standard and Oil-Blast Explosion Chamber Oil Circuit Breakers, R. M. Spurck, H. E. Strang. AIEE Transactions, volume 50, 1931, pages 513–21.

17. Development Trends in Circuit Interrupters, J. B. MacNeill. Electrical Engineering, volume 50, April 1931, pages 260–5.

18. Distribution of Energy Liberated in Oil Circuit Breaker; With a Contribution to Study of Arc Temperature, C. E. R. Bruce. Institution of Electrical Engineers *Journal* (London), volume 69, May 1931, pages 557–82.

19. Efficacy of Oil-Blast Principle Confirmed by Photography, D. C. Prince, E. B. Noel. *General Electric Review*, volume 34, December 1931, pages 722–4.

20. Gas Control the Crux in Oil Circuit Breakers, J. D. Hilliard. *Electrical World*, volume 98, August 1, 1931, pages 192–4.

21. How De-Ion and De-Ion-Grid Circuit Breakers Operate, H. N. Blackmon. *Power*, volume 74, August 4, 1931, pages 161–3.

22. Impulse High-Speed Circuit Breaker, W. K. Rankin. *General Electric Review*, volume 34, October 1931, pages 553–8.

23. Modern High-Speed Oil Circuit Breakers, E. B. Merriam. Canadian Electrical Association 41st Convention *Proceedings* (Toronto), 1931, pages 307–23.

24. Oil Blast Theory Proved Experimentally, D. C. Prince, E. J. Poitras. *Electrical World*, volume 97, February 28, 1931, pages 400–04.

25. Oil-Blast Circuit Breaker, D. C. Prince, W. F. Skeats. AIEE Transactions, volume 50, 1931, pages 506–12.

26. Oil Blast Extended to Other Breakers, D. C. Pri[n]ce, W. E. Paul. *Electrical World*, volume 98, September 19, 1931, pages 499–501.

27. Oil Blast Phenomena in Circuit Breakers, J. D. Hilliard. *Electrical World*, volume 98, July 11, 1931, pages 56–9.

28. Oil Circuit Breaker Tests—Philo 1930, Philip Sporn, H. P. St. Clair. AIEE Transactions, volume 52, 1931, pages 498–505.

29. Pressure Phenomena in Oil Circuit Breakers, W. M. Leeds. *Electric Journal*, volume 28, March 1931, pages 152–6.

1932

30. Engineering Features of a 2,000,000-Kva Oil Circuit Breaker, A. W. Hill. *Power Plant Engineering*, volume 36, September, 1932, pages 671–2.

31. Modern Performance From Old Breakers, H. G. MacDonald. *Electric Journal*, volume 29, December 1932, pages 573–5.

32. Practical Application of the Oil Blast Principle of Circuit Interruption, R. B. Spurck. AIEE Transactions, volume 51, 1932, pages 171–6.

33. Problems and Economies of Rebuilt Oil Switches, R. E. Rowley, Jr. *Electrical West*, volume 69, December 1, 1932, pages 231–3.

34. Recent Developments in Arc-Rupturing Devices, R. C. Van Sickle, W. M. Leeds. AIEE Transactions, volume 51, 1932, pages 177–84.

35. Results of Recent Investigations of the Interrupting Phenomena in Alternating-Current Arcs (in German), data collected by F. G. Ruegg, J. Kopeliowitsch, J. Biermanns, Association Suisse des Electriciens *Bulletin* (Zurich), volume 23, October 28, 1932, pages 565–92; data collected by O. Mayr, A. Roth, F. Kesselring, November 11, 1932, pages 605–29.

36. Roseland Substation 3,000,000-Kva Circuit Breakers, A. W. Hill. *Electric Journal*, volume 29, August 1932, pages 383–5.

37. Theory of Oil-Blast Circuit Breakers, D. C. Prince. AIEE Transactions, volume 51, 1932, pages 166–70.

38. To Stop Rain Leaks Into Oil Circuit Breaker Tanks, J. Elmer Housley. *Electrical World*, volume 100, December 3, 1932, page 756. Brief news note.

1933

39. Building a New Power System, F. S. Douglass, A. C. Monteith. *Electric Journal*, volume 30, February 1933, pages 55–9. One of a group of articles relating to tests on the power system of the Indianapolis Power and Light Company; see also references 47, 48, and 50 in this section.

40. Engineering Features of Oil Blast Action, D. C. Prince. *General Electric Review*, volume 36, August 1933, pages 361–3.

41. Fighting Oil Circuit Breaker Fires (abstract), G. S. Diehl. *Electrical World*, volume 102, July 29, 1933, page 153.

42. Interrupting-Capacity Tests on Circuit Breakers, R. M. Spurck, W. F. Skeats. AIEE Transactions, volume 52, 1933, pages 832–40.

43. Latest Development of Oil Breakers (in German), J. Biermanns. Verein Deutscher Ingenieure *Zeitschrift* (Berlin), volume 77, June 24, 1933, pages 673–8.

44. Oil-Blast Circuit Breakers of Medium Capacity, H. E. Strang. *General Electric Review*, volume 36, February 1933, pages 94–8.

45. Outdoor Expansion Breaker, F. Kesselring. (In German) *Siemens Zeitschrift* (Berlin), volume 13, November-December 1933, pages 309–15; (in English) *Siemens Review* (Berlin), volume 10, 1934, number 1, pages 1–7.

46. Some New Ideas in Oil Circuit Breaker Design (abstract), C. A. Church, N. R. Damon. Electrical Engineering, volume 52, April 1933, pages 247–8.

47. System Performance Tested With 600 Short Circuits, E. G. Ralston, E. H. Klemmer. *Electrical World*, volume 101, February 11, 1933, pages 192–5. One of a group of articles relating to tests on the power system of the Indianapolis Power and Light Company; see also references 39, 48, and 50 in this section.

48. Testing a Power System, A. W. Hill. *Electric Journal*, volume 30, March 1933, pages 95–7, 101. One of a group of articles relating to tests on the power system of the Indianapolis Power and Light Company; see also references 39, 47, and 50 in this section.

49. Timing Oil Breakers, G. F. Sargent, C. H. M. White. *Electrical World*, volume 102, August 19, 1933, page 241.

50. What the Tests Show, P. O. Langguth, R. M. Smith. *Electric Journal*, volume 30, March 1933, pages 98–101. One of a group of articles relating to tests on the power system of the Indianapolis Power and Light Company; see also references 39, 47, and 48 in this section.

1934

51. Decreased Operating Time Feature of Breaker Modernization, C. C. McKee. *Electrical West*, volume 73, September 1934, pages 32–3.

52. Development of Specific Interrupting Capacities in Oil Circuit Breakers (in German), H. C. Kloninger. *Elektrotechnik und Maschinenbau* (Vienna), volume 52, June 24, 1934, pages 286–91; July 1, 1934, pages 300–03.

53. Expulsion Oil Circuit Breaker, A. C. Schwager. AIEE Transactions, volume 53, 1934, July section, pages 1108–15.

54. Impulse Breaker Has Bushing Dimensions, D. C. Prince. *Electrical World*, volume 103, February 10, 1934, page 218.

55. Impulse Circuit Breaker. *Electrical News and Engineering* (Toronto), volume 43, September 15, 1934, pages 24–5, 40.

56. Oil Breakers Rated on New Duty-Cycle Basis. *Electrical World*, volume 103, April 14, 1934, page 545.

57. Orthojector Switch. *Electrician* (London), volume 113, August 17, 1934, page 209.

58. Speedier Switching Isolates Faults, W. M. Edson, R. E. Walsh. *Electrical World*, volume 103, August 11, 1934, pages 170–2.

59. Switching at Connors Creek Plant, A. P. Fugill. AIEE Transactions, volume 53, 1934, January section, pages 162–8.

60. Switching at Hudson Avenue Station, C. M. Gilt. AIEE Transactions, volume 53, 1934, pages 1741–8.

61. Switching at Long Beach Plant Number 3, A. A. Kroneberg, O. R. Bulkley, W. A. Andree. AIEE Transactions, volume 53, 1934, pages 1699–703.

62. Switching at Richmond Station, Raymond Bailey, F. R. Ford. AIEE Transactions, volume 53, 1934, January section, pages 156–61.

63. Switching at State Line Station, T. C. White. AIEE Transactions, volume 53, 1934, January section, pages 148–56.

64. To Interrupt High Voltage in Three Cycles, D. C. Prince, E. W. Boehne. *Electrical World*, volume 103, June 2, 1934, pages 795–8.

1935

65. Breakers Modernized With Minimum Ado, W. J. Lank. *Electrical World*, volume 105, October 12, 1935, page 54 (2462).

66. Building up Oil Circuit Breaker Contacts. *Power*, volume 79, May 1935, pages 367–8.

67. Circuit Breakers for Boulder Dam Line, D. C. Prince. AIEE Transactions, volume 54, 1935, April section, pages 366–72.

68. Circuit Breakers—Modern Portcullises. *Southern Power Journal*, volume 53, August 1935, page 19.

69. Further Development in Oil-Blast Circuit Breakers, D. C. Prince. *General Electric Review*, volume 38, September 1935, pages 415–21.

70. Inspection Practice With Oil Breakers. *Electrical World*, volume 105, July 6, 1935, page 52 (1708).

71. Maintenance Practice, II—Oil Circuit Breakers, C. W. Smith. *Electrical West*, volume 75, November 1935, page 25.

1936

72. Capacity Splits Voltage for Eight-Break Breaker, D. C. Prince. *Electrical World*, volume 106, July 4, 1936, pages 46–7 (2064–5).

73. Circuit Breakers for Boulder Dam Line, H. M. Wilcox, W. M. Leeds. AIEE Transactions, volume 55, 1936, June section, pages 626–35.

74. Convector Circuit Breaker in Operation on Distribution System of Western Switzerland, F. Werthmann. *Brown Boveri Review* (Baden), volume 23, September 1936, pages 215–20.

75. Development of Single-Break Oil Circuit Breaker for Metal-Clad Switchgear, D. R. Davies, C. H. Flurscheim.

Institution of Electrical Engineers *Journal* (London), volume 79, August 1936, pages 129–50.

76. Modernized Breakers Cut Upkeep $5,000, **J. H. Paget.** *Electrical World*, volume 106, February 29, 1936, page 78 (638).

77. Oil-Blast Breaker Arcs Photographed, **L. S. Hobson.** *Electrical World*, volume 106, November 7, 1936, pages 42–3, 98 (3478–9) (3534).

78. Oil Maintenance in Industrial Plant Breakers, **K. B. Humphrey.** *Power Plant Engineering*, volume 40, July 1936, page 409.

79. Oil-Poor Circuit Breaker With Oil Blast (in German), **O. Schwenk.** *Elektrotechnische Zeitschrift* (Berlin), volume 57, February 27, 1936, pages 229–31.

80. Proving Tests for High-Voltage Breakers, **H. M. Wilcox.** *Electrical World*, volume 106, December 19, 1936, pages 45–8 (3905–08).

81. Rejuvenating Oil Circuit Breakers With De-Ion Grids, **J. H. Paget.** *Electric Journal*, volume 33, August 1936, page 362.

82. The Ruptor—A Modern High-Efficiency Interrupting Device for Oil Circuit Breakers, **C. D. Ainsworth.** *Allis-Chalmers Electrical Review*, volume 1, September 1936, pages 9–12.

83. Special Tests on Impulse Circuit Breakers, **W. F. Skeats.** AIEE Transactions, volume 55, 1936, June section, pages 710–17; discussion, November section, pages 1236–7.

1937

84. Be Choosey About Oil Circuit Breakers and Their Accessories, **E. H. Beckert.** *Southern Power Journal*, volume 55, September 1937, pages 69–72; November 1937, pages 40–6; volume 56, January 1938, pages 44–9.

85. Capacitance Control of Voltage Distribution in Multibreak Breakers, **R. C. Van Sickle.** AIEE Transactions, volume 56, 1937, August section, pages 1018–24.

86. Expulsion Breaker Field Tests, **A. C. Schwager, V. A. Treat.** *Electrical World*, volume 107, February 27, 1937, pages 37–8, 112 (713–14, 788).

87. Oil Circuit Breakers for 500 Kv. *Electrical World*, volume 108, August 28, 1937, page 76 (720).

88. Oil Circuit Breaker Maintenance, **K. B. Humphrey.** *Power*, volume 81, January 1937, pages 14–16.

1938

89. Adapters Make Spare Bushings Interchangeable, **O. A. Pendleton.** *Electrical World*, volume 110, September 10, 1938, pages 43, 111 (707, 775).

90. Design and Test of High-Speed High-Interrupting-Capacity Railway Circuit Breaker, **W. F. Skeats.** AIEE Transactions, volume 57, 1938, July section, pages 359–63.

91. New Multibreak Interrupter for Fast-Clearing Circuit Breakers, **R. M. Spurck, H. E. Strang.** AIEE Transactions, volume 57, 1938, December section, pages 705–10.

92. Tests on Performance of a High-Speed Multibreak 138-Kv Oil Circuit Breaker, **Philip Sporn, H. P. St. Clair.** AIEE Transactions, volume 57, 1938, December section, pages 696–703.

1939

93. High-Speed Oil Circuit Breakers: Interpretation of "Singe Loop" Oscillograms. **E. E. I. Pilcher.** Institution of Electrical Engineers *Journal* (London), volume 85, July 1939, pages 143–9.

94. Multiple-Grid Breakers for High-Voltage Service, **J. B. MacNeill, A. W. Hill.** AIEE Transactions, volume 58, 1939, August section, pages 427–31.

95. New High-Speed 132-Kv Circuit Breaker, **C. H. Flurscheim.** *Engineer* (London), volume 167, April 21, 1939, pages 492–4.

1940

96. Breaker Inspection and Maintenance Schedules, **R. H. Johnson.** *Electrical West*, volume 84, June 1940, pages 134–5.

97. Mechanical Design of Circuit Breakers (abstract), **M. C. Hunter.** *Engineering* (London), volume 149, May 24, 1940, page 524.

98. Oil Circuit Breaker Maintenance, **C. H. Sammis.** *Southern Power and Industry*, volume 58, January 1940, page 56.

99. Past and Present in Oil Circuit Breaker Design, **L. B. Chubbuck.** *Electrical News and Engineering* (Toronto), volume 49, January 15, 1940, pages 28–9, 44.

Section C

Circuit Breakers—Water

1930

1. Expansion Breaker (in German), **F. Kesselring.** *Elektrotechnische Zeitschrift* (Berlin), volume 51, April 3, 1930, pages 499–508.

2. High-Capacity Breakers Without Oil (in German), **F. Kesselring.** *Siemens Zeitschrift* (Berlin), volume 10, June 1930, pages 364–8.

1931

3. Development of the Designs of Expansion Circuit Breakers (in German), **F. Kesselring.** Association Suisse des Electriciens *Bulletin* (Zurich), volume 22, May 29, 1931, pages 254–60.

4. Recent Test Results With Expansion Breakers (in German), **W. Kaufmann.** Verband Deutscher Elektrotechniker *Fachberichte* (Berlin), 1931, pages 42–5.

1935

5. Interrupting Tests on High-Power Circuit Breakers (in German), **B. von Borries, W. Kaufmann.** Verein Deutscher Ingenieure *Zeitschrift* (Berlin), volume 79, May 18, 1935, pages 597–604.

6. Research in the Development of Expansion Breakers (in German), **F. Kesselring.** *Elektrotechnik und Maschinenbau* (Vienna), volume 53, October 20, 1935, pages 493–5; October 27, 1935, pages 508–14.

1936

7. Achievements in the Construction of Expansion Breakers (in German), **L. Heinemeyer.** *Elektrotechnische Zeitschrift* (Berlin), volume 57, March 5, 1936, pages 281–4.

8. Modernized Breakers Cut Upkeep $5,000, **J. H. Paget.** *Electrical World*, volume 106, February 29, 1936, page 78 (638).

1940

9. High-Capacity "Hydro-Blast" Circuit Breaker for Central-Station Service, **W. F. Skeats, W. R. Saylor.** AIEE Transactions, volume 59, 1940, February section, pages 111–14.

10. Ten Years With Expansion Breakers (in German), **F. Kesselring.** *Elektrotechnische Zeitschrift* (Berlin), volume 61, June 6, 1940, pages 509–15.

Section D

Circuit Breakers—Rapid Reclosing

1929

1. Automatic-Reclosing High-Speed Circuit-Breaker Feeder Equipment for D-C Railway Service, **A. E. Anderson.** AIEE Transactions, volume 48, 1929, pages 554–62.

2. Automatic Reclosing of High-Voltage Circuits, **E. W. Robinson, S. J. Spurgeon.** AIEE Transactions, volume 48, 1929, pages 981–7.

1930

3. Circuit-Breaker Duty Affected by Speed, **C. L. Denault.** *Electrical World*, volume 96, November 15, 1930, pages 913–15.

1934

4. Automatic Reclosing of Oil Circuit Breakers, **A. E. Anderson.** AIEE Transactions, volume 53, 1934, January section, pages 48–53.

5. British Water Breakers Reclosed by Powder Explosion. *Electrical World*, volume 103, June 30, 1934, page 946.

6. Faster Reclosing Breakers Needed, **J. T. Logan.** *Electrical World*, volume 103, April 21, 1934, pages 571–2.

7. Mercury Reclosing Device for Automatically Reclosing Circuit Breakers, **A. E. Anderson.** *General Electric Review*, volume 37, October 1934, pages 462–7.

8. Oil Recloser for Distribution, **R. M. Spurck, D. K. Blake.** *Electrical World*, volume 104, October 27, 1934, pages 24–5 (730–1).

1935

9. Automatic Reclosing of 33-Kv Breakers, **H. H. Brown.** *Electric Light and Power*, volume 13, March 1935, pages 24–6.

10. Immediate Automatic Reclosing of Circuit Breakers, **W. M. Emmons.** *Electric Journal*, volume 32, March 1935, pages 114–18.

11. Immediate Initial Reclosure of Oil Circuit Breakers, **D. C. Prince, A. E. Anderson.** *General Electric Review*, volume 38, June 1935, pages 258–62.

12. Immediate Reclosure of 110-Kv Breakers, **J. T. Johnson, Jr., J. W. Graff.** *Electrical World*, volume 105, August 31, 1935, pages 21–3 (2101–03).

13. Oil Circuit Recloser and Its Operation, **L. S. Hobson.** *General Electric Review*, volume 38, November 1935, pages 511–13.

14. Reclosing Equipment for Medium- and Low-Voltage Circuits, **A. C. Abbott, E. Gray-Donald.** *Electrical News and Engineering* (Toronto), volume 44, July 1, 1935, pages 26–7.

15. Results With Quick Reclosure of 110-Kv Breakers, **J. T. Johnson, J. W. Graff.** *Electrical World*, volume 105, September 14, 1935, pages 38–40 (2214–16).

16. 32-Cycle Reclosure of 110-Kv Breaker, **J. H. Paget.** *Electrical World*, volume 105, March 2, 1935, page 66 (512).

1936

17. Carrier Relaying and Rapid Reclosing at 110 Kv, **R. E. Pierce, R. E. Powers, E. C. Stewart, G. E. Heberlein.** AIEE Transactions, volume 55, 1936, October section, pages 1120–9.

1937

18. One-Shot Reclosers Improve Service, Stop Complaints, **T. H. Kinnear, L. R. Patterson.** *Electrical West*, volume 79, September 1937, pages 63–4.

19. Reclosures Sectionalize Distribution Lines, **E. H. Beckert.** *Electrical World*, volume 107, April 10, 1937, pages 59, 112, 114 (1225, 1278, 1280).

20. Reclosing Scheme for Small Stations, **H. R. Moore.** *Electrical World*, volume 108, July 3, 1937, page 68 (68).

21. Ultrahigh-Speed Reclosing Expulsion Oil Circuit Breaker, **A. C. Schwager.** AIEE Transactions, volume 56, 1937, August section, pages 968–70.

22. Ultrahigh-Speed Reclosing of Transmission Lines, **D. C. Prince, Philip Sporn.** AIEE Transactions, volume 56, 1937, January section, pages 81–90.

1939

23. Experiences With Ultrahigh-Speed Reclosing of High-Voltage Transmission Lines, **C. A. Muller.** AIEE Transactions, volume 58, 1939, December section, pages 625–31.

24. Extinction of Short-Circuit Arcs by Removing Voltage for Short Times (in German), **W. Kaufmann.** *Elektrotechnische Zeitschrift* (Berlin), volume 60, March 2, 1939, pages 241–5.

1940

25. Adaptability of Compressed-Air Circuit Breakers for Rapid Reclosing Service (in German,) **G. Brockhaus.** *Elektrotechnische Zeitschrift* (Berlin), volume 61, February 29, 1940 pages 191–3.

26. High-Power Circuit Breakers for Rapid Reclosing Service (in German), **W. Kaufmann.** *Siemens Zeitschrift* (Berlin), volume 20, January-February 1940, pages 12–16.

27. Inertia Relay "Anticipates" to Facilitate Reclosure, **J. T. Logan, J. H. Miles.** *Electrical World*, volume 113, April 6, 1940, pages 69–72 (1061–4).

28. Proving of Rapid Reclosing in System Operation (in German), **R. Merkel.** *Elektrotechnische Zeitschrift* (Berlin), volume 61, August 22, 1940, pages 769–72.

29. Reclosing Air-Blast High-Speed Circuit Breakers. *Engineer* (London), volume 170, July 26, 1940, pages 62–3.

30. Reduction in the Number of Network Service Breakdowns by Means of Automatic Quick-Acting Reclosing of Circuit Breakers or by Using Protector Tubes, **H. Thommen.** *Brown Boveri Review* (Baden), volume 27, April 1940, pages 84–9.

Section E

Circuit Breakers—Recovery Voltages

1928

1. Extinction of an A-C Arc, J. Slepian. AIEE Transactions, volume 47, 1928, pages 1398–1407.

1929

2. High-Power Circuit Breakers Without Oil (in German), J. Biermanns. *Elektrotechnische Zeitschrift* (Berlin), volume 50, July 25, 1929, pages 1073–9; August 1, 1929, pages 1114–19.

3. Switching Large Powers (in German), F. Kesselring. *Elektrotechnische Zeitschrift* (Berlin), volume 50, July 11, 1929, pages 1005–13.

1930

4. Extinction of a Long A-C Arc, J. Slepian. AIEE Transactions, volume 49, 1930, pages 421–30.

1931

5. Calculation of the Natural Frequency of the Recovery Voltage and Its Significance to the Interrupting Capacity (in German), H. Gubler. Verband Deutscher Elektrotechniker *Fachberichte* (Berlin), 1931, pages 48–51.

6. Circuit Breaker Recovery Voltages—Magnitudes and Rates of Rise, R. H. Park, W. F. Skeats. AIEE Transactions, volume 50, 1931, pages 204–38.

7. Influence of the Transient Recovery Voltage on Circuit-Breaker Performance (in French), J. Kopeliowitsch. Association Suisse des Electriciens *Bulletin* (Zurich), volume 22, June 26, 1931, pages 312–17.

8. Reignition of Metallic A-C Arcs in Air, S. S. Atwood, W. D. Dow, W. Krausnick. AIEE Transactions, volume 50, 1931, pages 854–68.

9. System Configuration and Interrupting Capacity (in German), F. Kesselring. Verband Deutscher Elektrotechniker *Fachberichte* (Berlin), 1931, pages 51–4.

1933

10. Arc-Extinction Phenomena in High-Voltage Circuit Breakers, Studied With a Cathode-Ray Oscillograph, R. C. Van Sickle, W. E. Berkey. AIEE Transactions, volume 52, 1933, pages 850–7.

1935

11. Breaker Performance Studied by Cathode-Ray Oscillograms, R. C. Van Sickle. AIEE Transactions, volume 54, 1935, February section, pages 178–84.

12. Determination of Circuit Recovery Rates, E. W. Boehne. AIEE Transactions, volume 54, 1935, May section, pages 530–9.

13. Oil Circuit Breaker and Voltage Recovery Tests, E. J. Poitras, H. P. Kuehni, W. F. Skeats. AIEE Transactions, volume 54, 1935, February section, pages 170–8.

14. Some Notes on Rates of Rise of Restriking Voltage Subsequent to Interruption of Alternating-Current Power Circuits, C. H. Flurscheim. Institution of Electrical Engineers *Journal* (London), volume 76, March 1935, pages 323–37.

1936

15. Rise of the Recovery Voltage After Circuit-Breaker Interruption in Systems (in German), G. Hameister. *Elektrotechnische Zeitschrift* (Berlin), volume 57, September 3, 1936, pages 1025–8.

16. Special Tests on Impulse Circuit Breakers, W. F. Skeats. AIEE Transactions, volume 55, 1936, June section, pages 710–17.

1937

17. Calculation of the Oscillations of the Recovery Voltage After the Rupture of Short Circuits, W. Wagner, J. K. Brown. *Brown Boveri Review* (Baden), volume 24, November 1937, pages 283–302.

18. Investigations Made in 1936 of Recovery Voltage and Dielectric Strength (in French), E. Krohne, F. Kesselring. International Conference on Large High-Voltage Electric Systems (CIGRE, Paris), *Compte Rendu des Travaux*, 1937, volume 1, report 112, 21 pages.

19. Restriking Voltage and Its Import in Circuit-Breaker Operation, H. Trencham, K. J. R. Wilkinson. Institution of Electrical Engineers *Journal* (London), volume 80, May 1937, pages 460–8.

20. Restriking Voltage Characteristics and Fault Currents, L. Gosland. *World Power* (London), volume 27, May 1937, pages 160–72.

21. System Recovery Voltage Determination by Analytical and A-C Calculating Board Methods, R. D. Evans, A. C. Monteith. AIEE Transactions, volume 56, 1937, June section, pages 695–705.

1938

22. Performance of Circuit Breakers and Power-Disconnecting Switches in Laboratories and in Service (in German), G. Hameister. *Elektrotechnische Zeitschrift* (Berlin), volume 59, June 9, 1938, pages 605–08.

1939

23. Effect of Restriking on Recovery Voltage, C. Concordia, W. F. Skeats. AIEE Transactions, volume 58, 1939, August section, pages 371–6.

24. Equivalent Circuits of Transformers and Reactors to Switching Surges, L. V. Bewley. AIEE Transactions, volume 58, 1939, pages 797–802.

25. Influence of Resistance on Switching Transients, R. C. Van Sickle. AIEE Transactions, volume 58, 1939, August section, pages 397–404.

26. Measurements and Calculations on Restriking Voltage Transients at a Substation Fed by Single-Core Cables, L. Gosland. Institution of Electrical Engineers *Journal* (London), volume 84, February 1939, pages 269–86.

27. Overvoltages During Power-System Faults, E. Clarke, S. B. Crary, H. A. Peterson. AIEE Transactions, volume 58, 1939, August section, pages 377–85.

28. Power-System Transients Caused by Switching and Faults, R. D. Evans, A. C. Monteith, R. L. Witzke. AIEE Transactions, volume 58, 1939, August section, pages 386–96.

29. Power-System Voltage Recovery Characteristics, H. A. Peterson. AIEE Transactions, volume 58, 1939, August section, pages 405–13.

1940

30. Calculation and Experiment on Transformer Reactance in Relation to Transients of the Restriking Voltage, **L. Gosland, W. F. M. Dunne.** Institution of Electrical Engineers *Journal* (London), volume 87, August 1940, pages 163–77.

31. Restriking Voltage Characteristics Under Various Fault Conditions at Typical Points on the Network of a Large City Supply Authority, **L. Gosland**, Institution of Electrical Engineers *Journal* (London), volume 86, March 1940, pages 248–74.

Section F

Circuit Breakers—General and Miscellaneous

1929

1. Control Circuits for Power Stations, **S. Q. Hayes.** *Power*, volume 69, March 12, 1929, pages 431–3.

1930

2. Calculation of Mechanical Performance of Oil Circuit Breakers (abstract), **A. C. Schwager.** AIEE Journal, volume 49, October 1930, pages 826–9.

3. Proving Ground for Circuit Breakers, **D. F. Miner.** *Electric Journal*, volume 27, November 1930, pages 625–30.

4. Selecting Breaker Speeds for Stable Operation, **R. D. Evans, W. A. Lewis.** *Electrical World*, volume 95, February 15, 1930, pages 336–40.

5. Straight-Line Motion for Oil Circuit Breaker, **J. W. W. Ow.** *Machinery*, volume 36, May 1930, pages 676–7.

1932

6. Electric Arc in Circuit Interrupters, **J. Slepian.** Franklin Institute *Journal*, volume 214, October 1932, pages 413–42; (in French) International Electrical Congress (Paris) *Comptes Rendus*, volume 6, section 4, 1932, pages 1–31.

7. Extinction of A-C Arcs in Turbulent Gases, **T. E. Browne, Jr.** AIEE Transactions, volume 51, 1932, pages 185–91.

8. High-Power Interrupting-Capacity Testing Station of the General Electric Company, **G. F. Davis**, *General Electric Review*, volume 35, February 1932, pages 99–106.

9. Impulse Testing Machine for Circuit-Breaker Tanks. *Engineering* (London), volume 134, July 1, 1932, page 8.

10. Service Continuity Promoted by Rapid Breaker Reclosure, **Robert Treat, H. C. Verwoert.** *Electrical World*, volume 100, August 6, 1932, pages 172–5; also "Year's Experience Justifies Instantaneous Reclosing" (letter), **E. E. George**, October 29, 1932, page 606.

1933

11. Breaker Capacity Ratings. *Electrical Times* (London), volume 84, September 28, 1933, pages 405–06.

12. Circuit-Interruption Primer, **W. M. Leeds, T. E. Browne, Jr.** *Electrical Journal*, volume 30, March 1933, pages 106–07; April 1933, pages 156–9.

13. Curve-Drawing Device Tests Oil-Breaker Travel, **M. S. Schneider, S. Goldsmith.** *Electrical World*, volume 102, October 7, 1933, page 474.

14. Designs of Current-Carrying Contacts in Modern Switchgear, **R. Paxton, H. E. Strang.** *General Electric Review*, volume 36, December 1933, pages 524–8.

15. Extinction of an Alternating-Current Arc in a Gas Stream (in German), **J. Slepian.** *Elektrotechnik und Maschinenbau* (Vienna), volume 51, April 2, 1933, pages 180–4.

16. Power for Circuit-Breaker Solenoids, **W. W. Brainard.** *Electric Journal*, volume 30, May 1933, pages 189–91.

17. Scheduling Breaker Inspection Reduces Maintenance Costs, **T. J. Allen, W. P. Speir.** *Electrical World*, volume 101, February 25, 1933, pages 266–8.

18. Short-Circuit Test Reports. *Electrical Times* (London), volume 84, September 28, 1933, pages 406–07.

1934

19. Circuit Interruption, **J. Slepian.** *Electrical News and Engineering* (Toronto), volume 43, May 1, 1934, pages 18–19.

20. Compact Timing Device Facilitates Breaker Timing, **G. H. Wintersteen.** *Electrical World*, volume 104, August 4, 1934, page 150.

21. Electric Power Switching, **A. H. Lovell.** AIEE Transactions, volume 53, 1934, January section, pages 147–8.

22. Faster Tripping Speeds. *Electrical World*, volume 103, June 23, 1934, pages 908–09.

23. Portable Schering Bridge for Field Tests, **C. F. Hill, T. R. Watts, G. A. Burr.** AIEE Transactions, volume 53, 1934, January section, pages 176–82.

24. Steam-Blast Circuit Breakers. *Power Plant Engineering*, volume 38, February 1934, page 107.

25. Testing Bushings and Insulation by Power-Factor Method, **I. W. Gross, H. E. Turner.** *Electrical World*, volume 103, January 13, 1934, pages 68–73.

26. Three Ways to Insure Industrial Oil Circuit Breaker Adequacy, **R. I. Powers.** *Electrical World*, volume 103, June 23, 1934, page 920.

27. Transfer Feeder Faults to One Breaker, **L. F. Woodruff, J. E. Mulligan.** *Electrical World*, volume 103, March 31, 1934, pages 464–5; also "One Breaker Enough for Two or More Feeders?" (letter), **C. H. Sanderson**, May 5, 1934, page 664; "Fault Transfer Switch Has Merits" (letter), **L. F. Woodruff, J. E. Mulligan**, volume 104, July 21, 1934, page 90.

28. Trends in Power Control, **C. C. Garrard.** *Electrical Review* (London), volume 115, November 16, 1934, pages 673–4.

1935

29. Calculations of Arc Energy From Oscillograms, **W. M. Leeds.** *Electric Journal*, volume 32, February 1935, pages 78–80.

30. Enclosed Circuit Breakers for Continuity of Service in the New Philadelphia Post Office, **A. W. Lundstrom.** *General Electric Review*, volume 38, December 1935, pages 576–8.

31. European Breaker Practice Contrasts With Domestic (letter), **D. C. Prince.** *Electrical World*, volume 105, December 21, 1935, page 17 (2989).

32. Give Circuit Breakers a Break, **H. J. Lingal.** *Factory Management and Maintenance*, volume 93, May 1935, pages 221–2.

33. HIGH-VOLTAGE BUSHINGS TESTED IN PLACE, C. F. Benham. *Electrical World*, volume 105, September 28, 1935, pages 29–30, 77 (2327–8, 2375).

1936

34. BUSHING POWER-FACTOR TESTS SHOW FAILURE CAUSES, E. L. Schlottere. *Electrical World*, volume 106, March 28, 1936, pages 34–7 (894–7).

35. CONTROL OF SHORT CIRCUITS CUTS COSTS, H. C. Tice. *Electrical World*, volume 106, December 5, 1936, pages 38–40 (3762–4).

36. DEVELOPMENT OF THE ARC-RUPTURING DEVICES OF MODERN CIRCUIT BREAKERS (in German), H. Puppikofer. Association Suisse des Electriciens *Bulletin* (Zurich), volume 27, December 25, 1936, pages 749–64.

37. EUROPEAN DEVELOPMENTS IN CIRCUIT INTERRUPTION, D. I. Vinogradoff. *Electric Journal*, volume 33, March 1936, pages 129–33.

38. MODERN HIGH-VOLTAGE BREAKERS (in German), A. Roth. *Elektrotechnik und Maschinenbau* (Vienna), volume 54, October 4, 1936, pages 469–73.

1937

39. CALCULATING LOW-VOLTAGE SYSTEM SHORT CIRCUITS. *Electrical News and Engineering* (Toronto), volume 46, November 1, 1937, page 36.

40. CAPACITY STORED ENERGY FOR CIRCUIT-BREAKER TRIPPING, L. W. Dyer. *Electric Journal*, volume 34, May 1937, pages 193–4.

41. FUSE–BREAKER CORRELATION FIXED BY FAULT RATIO, P. E. Benner. *Electrical World*, volume 108, December 18, 1937, pages 53–4, 115 (2033–4, 2095).

Air Switches

1928

1. PROPER LOCATION OF DISCONNECTING SWITCHES INSURES SAFETY, W. Specht. *Electrical World*, volume 91, May 5, 1928, page 907.

2. ECONOMY OF FACTORY-ASSEMBLED DISCONNECTING SWITCHES, George F. Heidenreich. *Electrical World*, volume 92, November 10, 1928, page 941.

3. SUGGESTED LINE-SECTION SWITCH, J. A. Reynolds, *Electrical World*, volume 92, September 22, 1928, page 570.

4. TRANSFORMER DISCONNECTING SWITCHES IN OIL-FILLED POTHEADS, Wellen H. Colburn. *Electrical World*, volume 91, April 28, 1928, pages 866–7.

1929

5. DESIGN AND CONSTRUCTION OF ALTERNATING-CURRENT SWITCHING INSTALLATIONS FOR POWER STATIONS (book, in German), J. Waltjen. Springer, Berlin, 1929. Air-break switches, page 115.

1930

6. HIGH-VOLTAGE LOW-CURRENT FUSES AND SWITCHES, Roy Wilkins. AIEE TRANSACTIONS, volume 49, 1930, pages 96–8.

1931

7. CHARACTERISTICS OF MOTOR-OPERATED SWITCHES (in German), A. S. Vinzce. *Elektrotechnik und Maschinenbau* (Vienna), volume 49, March 15, 1931, pages 201–04.

8. DISCONNECTING-SWITCH CONTACTS FOR HIGH SHORT-CIRCUIT CURRENTS (in German), C. Cippitelli, O. Schwenk. *Elektrotechnische Zeitschrift* (Berlin), volume 52, February 26, 1931, pages 263–4.

9. DISCONNECTING SWITCHES FOR INDOOR SERVICE, S. Gersmann. *Electric Journal*, volume 28, February 1931, pages 96–8.

10. ELIMINATION OF DISCONNECTING-SWITCH HAZARD, J. Auchincloss. *Power Plant Engineering*, volume 35, September 15, 1931, page 938.

11. NEW AEG STAR-DELTA SWITCH (in German), W. Höpp. Verband Deutscher Elektrotechniker *Fachberichte*, 1931, pages 155–7.

12. OUTDOOR SECTIONALIZING SWITCH FOR 2,000 AMPERES DIRECT CURRENT AT 3,000 VOLTS (in Italian). *Bolletino Tecnico*, volume 4, June 1931, pages 1–4. A Magrini horn-gap switch.

13. POLE-TOP SWITCHES REDESIGNED FOR ALL-WOOD CONSTRUCTION, F. E. Andrews. *Electrical World*, volume 97, January 31, 1931, page 226.

14. ROTATING BUS-BAR DISCONNECTORS IN OUTDOOR SUBSTATIONS (in French), H. W. Young and A. Alsaker. International Conference on Large High-Voltage Electric Systems (CIGRE, Paris), *Compte Rendu des Travaux*, 1931, volume 1, pages 770–84.

1932

15. AUTOMATIC AIR-BREAK SWITCH REDUCES OUTAGE TIME, R. E. Greene. *Electrical World*, volume 100, October 15, 1932, pages 541–2. A pole-top switch designed by The Detroit Edison Company.

16. INTERLOCKING OF DISCONNECT SWITCHES AND OIL CIRCUIT BREAKERS, LOS ANGELES GAS AND ELECTRIC CORPORATION, F. H. Streit. *Electrical West*, volume 68, May 15, 1932, pages 329–31.

17. NOVEL AIR-BREAK SWITCH FOR 11,000-VOLT OVERHEAD LINE. *Electrician* (London), volume 108, January 8, 1932, page 48. A Metropolitan-Vickers development.

18. RECENT DEVELOPMENTS IN AIR-BREAK SWITCHING PRACTICE, W. J. Gilson. *Electrical News and Engineering* (Toronto), volume 41, November 15, 1932, pages 34–7, 49.

19. RUPTURING CAPACITY OF AIR-BREAK SWITCHES, W. H. Thompson. *Metropolitan-Vickers Gazette* (Manchester, England), volume 13, April 1932, pages 224–7.

1933

20. COMPRESSED AIR OPERATION FOR ELECTRIC SWITCHGEAR (in German), I. Sihler. *Elektrotechnische Zeitschrift* (Berlin), volume 54, December 21, 1933, pages 1237–9.

21. CONTROL AND INSTRUMENT SWITCHES, H. J. Crabbs. *Electric Journal*, volume 30, February 1933, pages 62–5.

22. D-C SWITCHGEAR FOR VERY HEAVY CURRENTS (in German),

O. Burawoy. *AEG Mitteilungen*, November 1933, pages 237–9. Deals in part with isolating and disconnecting switches.

23. Design of Current-Carrying Contacts in Modern Switchgear, **R. Paxton, H. E. Strang.** *General Electric Review*, volume 36, December 1933, pages 524–8.

24. Elements of Switchgear Design (book), **F. Kesselring.** Pitman, New York, 1933. Air-break switches, page 114*f*.

25. High-Voltage Star-Delta Switch, **B. Lang.** (In German) *AEG Mitteilungen*, May 1933, pages 97–100; (in English) *AEG Progress*, number 3, 1933, pages 44–5.

26. New Traction-Tapping Switch, **W. Lüthi.** *Brown Boveri Review* (Baden), volume 20, May-June 1933, pages 94–6.

27. Switch Contacts of Silver (in German), **W. Höpp.** *Elektrotechnische Zeitschrift* (Berlin), volume 54, March 2, 1933, pages 203–05.

28. Switch Rating and Operation Frequency (in German), **H. Franken.** *Elektrotechnische Zeitschrift* (Berlin), volume 54, November 30, 1933, pages 1163–4. Deals with small switches—1 to 15 kw.

1934

29. Air-Break Sectionalizing Switches for Ring Primary, **C. A. Matthews.** *Electrical World*, volume 103, January 27, 1934, pages 146–7.

30. Automatic Switch for High Nominal Currents (in German), **A. Müller.** *Siemens Zeitschrift* (Berlin), volume 14, March 1934, pages 73–6.

31. D-C Contactor (in German), **R. Edler.** *Elektrotechnische Zeitschrift* (Berlin), volume 55, March 29, 1934, pages 316–17. Describes the mechanism of a remote-controlled switch for currents up to 8,000 amperes at 500 volts.

32. Electromagnetic Auxiliary Switches (in German), **H. Appel.** Verband Deutscher Elektrotechniker *Fachberichte* (Berlin), 1934, pages 47–50. Description of various switches within maximum limits of 550 volts, 25 amperes.

33. Feeder-Fault Transfer Switch, **L. F. Woodruff, J. E. Mulligan.** *Electrical World*, volume 103, March 31, 1934, pages 464–5.

34. Isolating Switches for Pole Mounting. *Engineer* (London), volume 157, May 4, 1934, pages 462–3; *Engineering* (London), volume 137, May 25, 1934, page 611.

35. New Gate-End Starter; Remote-Controlled Air-Break Flameproof Contactor Unit for Fiery Mines. *Electrician* (London), volume 113, July 13, 1934, pages 72–3.

36. Special Application of the Vent Principle in Oil-Free Power Switches (in German), **L. Haag, O. Schwenk.** *Elektrotechnische Zeitschrift* (Berlin), volume 55, March 1, 1934, pages 211–13.

37. Star-Delta Rotary Switch (in German), **R. Edler.** *Elektrotechnik und Maschinenbau* (Vienna), volume 52, December 2, 1934, pages 564–6.

1935

38. Circuit Breakers and Disconnecting Switches for Low-Voltage Enclosed Equipment (in French), **M. P. Reboul.** *Revue d'Electricité et de Mécanique* (Paris), Number 44, November-December 1935, pages 14–23; number 45, January-February 1936, pages 18–24.

39. Delta-Star High-Voltage Balanced-Blade Switches. *Power Plant Engineering*, volume 39, December 1935, page 706.

40. Isolating Switch (in German), **O. Mayr.** *Elektrotechnische Zeitschrift* (Berlin), volume 56, October 31, 1935, pages 1189–92.

41. New Trigger Circuit for Closing a Switch, **J. J. Ruiz.** AIEE Transactions, volume 54, 1935 (December section), pages 1405–07.

42. Opening of Isolating Switches on Load (in French), **H. Josse.** Société Française des Electriciens *Bulletin* (Malakoff, France), volume 5, November 1935, pages 1199–1212.

43. Opening of Isolating Switches on Load (in French), **E. Masson.** Société Française des Electriciens *Bulletin* (Malakoff, France), volume 5, November 1935, pages 1213–22.

44. Packet Switches (in German), **R. Edler.** *Archiv fuer Elektrotechnik* (Berlin), volume 29, August 1, 1935, pages 531–55.

45. Star-Delta Starter Switches, **S. Hopperwieser.** *Brown Boveri Review* (Baden), volume 22, December 1935, pages 243–5. For motors up to 400 amperes, 500 volts.

46. 287-Kv Three-Pole Motor-Operated Switches of Boulder Dam—Los Angeles 275-Kv Line, California, **H. W. Young, E. S. Cornell.** International Conference on Large High-Voltage Electric Systems (CIGRE, Paris), *Compte Rendu des Travaux*, 1935, volume 1, report 142, 11 pages.

1936

47. Contractors and Cam Switches for Direct Current, **P. Friebel.** *ASEA Journal* (Västerås, Sweden), volume 13, January 1936, pages 2–5.

48. Electric Switches and Switch Mountings, **B. B. Ramey.** *Product Engineering*, volume 7, May 1936, pages 190–1; July 1936, pages 274–5. For motor-driven tools.

49. Horsepower-Rated Switch Selection, **H. B. Smith.** *Electrical Contracting*, volume 35, September 1936, pages 10–12.

50. Interlocking of High-Voltage Disconnecting Switches (in German), **G. Meiner.** *AEG Mitteilungen*, August 1936, pages 284–8

51. Magnetic Extinguishing of Electric Arcs in D-C Switches (book, in German), **E. Wurth.** Konrad Triltsch, Wurzburg, 1936. 85 pages. Includes a reference list of 22 items.

52. 150,000-Ampere Contactor, **W. Schaelcklin.** *Electric Journal*, volume 33, August 1936, pages 363–6. Used in pipe-welding equipment.

53. Power Isolator (in German), **E. Krohne** and others. *Elektrotechnische Zeitschrift*, volume 57, August 20, 1936, pages 961–7.

54. Safe High-Tension Disconnect. *Engineering and Mining Journal*, volume 137, October 1936, page 506.

55. 287-Kv Boulder Dam Disconnecting Switches, **A. J. Bowie, C. P. Garman.** AIEE Transactions, volume 55, 1936 (June section), pages 582–9.

56. Winter Operation of Outdoor High-Voltage Air-Break Switches, **P. J. Croft.** *Electrical News and Engineering* (Toronto), volume 45, July 1, 1936, pages 19–21.

1937

57. Adaptability of Disconnecting Switches to Operation With Nominal Currents (in Russian), **B. V. Malevinskii.** *Elektrichestvo* (Leningrad), number 4, February 1937, pages 37–42.

58. Air-Break Change-Pole Switch. *Engineering* (London), volume 143, June 11, 1937, page 678; also "New Change-Pole Switches," *Engineer* (London), volume 163, April 9, 1937, page 428.

59. Air-Break High-Voltage Reversing Switch, With Pneumatic Control, for Three-Phase Mine Hoists (in

French), *Revue d'Electricité et de Mécanique* (Paris), March-April 1937, pages 37–8.

60. ELECTROMAGNETICALLY ACTUATED REMOTE-CONTROL SWITCHES (in German), **R. Edler.** *Elektrotechnik und Maschinenbau* (Vienna), volume 55, October 24, 1937, pages 521–31. Includes a reference list of 126 items.

61. FURTHER DEVELOPMENT OF COMPRESSED-AIR BREAKER WITH DOUBLE-ACTING AIR FLOW (in German), **O. Schwenk.** Verband Deutscher Electrotechniker *Fachberichte* (Berlin), volume 9, 1937, pages 90–2.

62. GENERAL ELECTRIC ROTATING-CAM SWITCHES. *General Electric Review*, volume 40, March 1937, page 164.

63. INDOOR SWITCHGEAR FOR VOLTAGES ABOVE 30 KV (in German), **W. Schrinner.** *Elektrotechnische Zeitschrift* (Berlin), volume 58, December 16, 1937, pages 1338–40.

64. NAMCO SUPERSENSITIVE LINE-VOLTAGE SWITCH. *Machinery*, volume 43, August 1937, page 818.

65. OUTDOOR HIGH-VOLTAGE SWITCHGEAR (book), **R. W. Todd, W. H. Thompson.** Pitman, London and New York, 1937. 436 pages. Air-break switches, pages 99–122.

66. PNEUMATIC CONTROL FOR CIRCUIT BREAKERS AND ISOLATORS (in French), **J. Mosebach.** *Revue Générale de l'Electricité* (Paris), volume 41, April 3, 1937, pages 433–41.

67. POINT CONTACTS FOR HEAVY CURRENTS; USE OF SILVER IN SWITCHES, **W. H. Lindae.** *Electrical World*, volume 108, July 31, 1937, page 414.

68. RECENT DEVELOPMENTS IN LOW-VOLTAGE SWITCHGEAR (in German), **D. Müller-Hildebrand.** *Siemens Zeitschrift* (Berlin), volume 17, October 1937, pages 505–16. Includes some material on air-break switches.

69. SWITCHING TESTS WITH HORN-GAP DISCONNECTING SWITCHES ON POLES (in German), **M. Süberkrüb.** *Elektrische Bahnen*, volume 13, October 1937, pages 231–5.

1938

70. AIR-BREAK CONTACTORS FOR THE CONTROL OF LARGE HIGH-VOLTAGE MOTORS (in German), **F. Kassau.** Verband Deutscher Elektrotechniker *Fachberichte* (Berlin), volume 10, 1938, pages 42–6.

71. BBC DISCONNECTING SWITCHES (in German), **F. Parschalk.** *BBC Nach.*, volume 25, October-December 1938, pages 137–42. Construction and performance.

72. BROWN BOVERI ON-LOAD DISCONNECTING SWITCH, **H. Thommen.** *Brown Boveri Review* (Baden), volume 25, July 1938, pages 151–4.

73. DEVELOPMENT OF LOW-VOLTAGE SWITCHGEAR (in German), **H. Franken.** *Elektrotechnische Zeitschrift* (Berlin), volume 59, May 5, 1938, pages 461–4.

74. "DISC TYPE" SWITCHES (in German), **R. Edler.** *Elektrotechnik und Maschinenbau* (Vienna), volume 56, December 11, 1938, pages 669–72; December 18, 1938, pages 686–90. Describes a systematic method of designing switches.

75. DUO-MOTION OUTDOOR AIR SWITCH. *General Electric Review*, volume 41, July 1938, page 339.

76. ELECTRICALLY OPERATED HIGH-TENSION STATOR-REVERSING SWITCH. *Engineering* (London), volume 145, March 25, 1938, page 342. Constructed by General Electric Company, Ltd., England.

77. FLAMEPROOF AIR-BREAK-SWITCH STARTERS. *Metropolitan-Vickers Gazette* (Manchester, England), volume 17, October 1938, pages 384–5. For squirrel-cage motors.

78. IMPROVED LOW-TENSION INDUSTRIAL SWITCHGEAR. *Engineer* (London), volume 165, February 11, 1938, page 171.

79. J. AND P. SWITCHGEAR BOOK (book), **R. T. Lythall.** Third edition. Johnson and Phillips, Ltd., London, 1938.

80. KNIFE-SWITCH MAINTENANCE, **S. H. Coleman.** *Factory Management and Maintenance*, volume 96, July 1938, page 108.

81. LOW-TENSION DISTRIBUTION SYSTEMS IN MINES AND INDUSTRIAL AND CHEMICAL PLANT (in German), **A. Stormanns.** Verein Deutscher Ingenieure *Zeitschrift* (Berlin), volume 82, February 26, 1938, pages 254–50.

82. LOW-VOLTAGE SWITCHGEAR (in German), **Franz Denk.** Verein Deutscher Ingenieure *Zeitschrift* (Berlin), volume 82, October 22, 1938, page 1251–8. Illustrated account of construction and performance of low-voltage switches, contactors, disconnectors, etc.

83. RECENT PROGRESS IN THE PNEUMATIC CONTROL OF DISCONNECTING SWITCHES (in French), **J. Mosebach.** *Revue Générale de l'Electricité* (Paris), volume 44, September 3, 1938, pages 268–73.

84. REMOTE-CONTROLLED REVERSING SWITCH AND WIRING METHODS FOR ITS USE (in German), **F. Lucan.** *Elektrotechnische Zeitschrift* (Berlin), volume 59, March 10, 1938, pages 261–4.

85. SPECIAL TRIPS FOR AEG SWITCHES (in German), **H. Ude.** *AEG Mitteilungen*, September 1938, pages 463–6.

86. WE KEEP FUMES AWAY FROM CONTROLS, **L. E. Du Bey.** *Factory Management and Maintenance*, volume 96, April 1938, pages 65–6. "Putting all switches, fuses, and starters in isolated rooms solved the problem of how a paint factory could best eliminate fire hazards and keep equipment clean."

1939

87. ENGLISH ELECTRIC COMPANY'S AIR-BREAK SWITCH. *Engineering* (London), volume 147, March 3, 1939, pages 244–5.

88. FLAMEPROOF AIR-BREAK SWITCHGEAR. *Engineering* (London), volume 147, April 14, 1939, page 446; *Engineer* (London), volume 167, April 21, 1939, page 499. Built by A. Reyrolle and Company, England, for 100 amperes at 600 volts.

89. LOCKING DEVICES FOR DISCONNECTING SWITCHES (in German), **B. Fleck.** *AEG Mitteilungen*, March 1939, pages 178–82.

90. MOTOR DRIVE FOR LOW-TENSION SWITCHGEAR (in German), **W. Herden.** *Elektrotechnische Zeitschrift* (Berlin), volume 60, March 9, 1939, pages 293–4. Recent AEG designs are described.

91. MOTOR-OPERATED SPRING-CLOSING SWITCHGEAR MECHANISM. *Engineer* (London), volume 167, January 27, 1939, page 134. Built by Switchgear and Cowans, Ltd., Manchester, England.

92. "60-LINE" CONTACTS AID SWITCH OPERATION. *Electrical World*, volume 112, October 7, 1939, page 1052. Westinghouse disconnecting switch.

93. THE SWITCHGEAR HANDBOOK, VOLUME I, APPARATUS (book), **W. A. Coats and H. Pearce.** Pitman, New York, 1939. 190 pages. Air-break switches, page 115*f*.

1940

94. IMPROVEMENTS IN 287.5-KV DISCONNECTS. *Electrical World*, volume 114, November 2, 1940, page 98 (1352).

95. SWITCH DESIGN ELIMINATES BRAIDS, **H. W. Young.** *Electrical World*, volume 114, July 13, 1940, page 86 (110).

96. SWITCH IMPULSE STRENGTHS PARALLEL INSULATOR VALUES, **Elias S. Cornell.** *Electrical World*, volume 114, November 30, 1940, pages 64–5 (1630–1).

Section I

Bus Bars

1928

1. Bus Stresses Under Short Circuits. *Electrical World*, volume 92, September 22, 1928, pages 564–5.

2. Concrete Bus Structure Tests, **W. A. Kates.** *Electrical World*, volume 91, June 30, 1928, pages 1379–82.

3. Importance of Flexibility in High-Tension Bus, **A. B. Dibner.** *Electrical World*, volume 92, November 10, 1928, page 946.

4. Joining Aluminum Bus Bars, **W. E. Warner.** *Power Plant Engineering*, volume 32, June 15, 1928, page 672.

5. Porcelain Bushings Support Tubular Bus. *Electrical World*, volume 91, March 17, 1928, page 551.

6. Short-Cut Methods of Calculating Stresses in Bus Structures, **W. Specht.** *General Electric Review*, volume 31, August 1928, pages 413–18.

7. Spacing Bus Bars for Safe Voltage Clearance, **M. Kushlan.** *Electrical World*, volume 92, October 6, 1928, pages 681–2.

1929

8. Current-Carrying Capacity of Bus Bars, **H. W. Pabst.** *Electrical World*, volume 94, September 21, 1929, pages 569–72.

9. Features of A-C and D-C Bus-Bar Design, **T. H. McCauley.** *Power Plant Engineering*, volume 33, April 15, 1929, pages 474–7.

1930

10. Design of Bus Bars and Connections for Indoor and Outdoor Substations, **H. E. Hutter.** *Electrical Review* (London), volume 106, May 9, 1930, pages 859–61; volume 107, August 8, 1930, pages 209–11. Includes material on methods of supporting the conductors.

11. Efficient Utilization of Conductor Material in Bus-Bar Sections, **C. Dannatt, S. W. Redfearn.** *World Power* (London), volume 14, November 1930, pages 397–400; December 1930, pages 492–6.

12. Fault Ground Bus—Its Use and Design in Brunot Island Switchhouse of Duquesne Light Company, **R. M. Stanley, F. C. Hornibrook.** AIEE Transactions, volume 49, 1930, pages 201–11.

13. Joints for Aluminum Bus Bars, **W. E. Warner.** *Electrical Review* (London), volume 106, January 24, 1930, page 159.

1931

14. Aluminum Bus Bars Resist Power Arcs, **J. D. Porter.** *Electrical World*, volume 98, July 18, 1931, pages 104–05.

15. Bus-Bar Design and Construction. *Power Plant Engineering*, volume 35, January 1, 1931, pages 34–5.

16. Current-Carrying Capacity of Base Cylindrical Conductors for Indoor and Outdoor Service, **C. W. Frick.** *General Electric Review*, volume 34, August 1931, pages 464–71.

17. Current-Carrying Capacity of Hollow Conductors, **H. W. Pabst.** *Electric Journal*, volume 28, July 1931, pages 411–14.

18. Electrodynamic Effects of Short Circuits on the Porcelain Supports of Substation Bus Bars (in French), **H. Josse.** International Conference on Large High-Voltage Electric Systems (CIGRE, Paris), *Compte Rendu des Travaux*, 1931, volume 1, pages 755–69.

19. Structural-Slope Conductors Show Increased Efficiencies, **H. W. Pabst, D. I. Bohn.** *Electrical World*, volume 98, September 5, 1931, pages 418–19.

20. Tubular Copper Bus Simplified Service Vault. *Electrical World*, volume 98, September 26, 1931, page 543.

1932

21. Bus Bars and Bus-Bar Connections in Air, Oil, or Compound. British Standards Association, B.S. number 159, London, 1932. An addendum was issued in 1938.

22. Bus Spacings and Ground Clearances. *Electrical World*, volume 99, January 16, 1932, page 136.

23. Calculation of Inductance and Current Distribution in Low-Voltage Connections to Electric Furnaces, **C. C. Levy.** AIEE Transactions, volume 51, 1932, pages 903–13.

24. Carrying Capacity of Inclosed Busses, **A. P. Fugill.** *Electrical World*, volume 99, March 19, 1932, pages 539–40.

25. Channel Bus for Office-Building Risers, **C. A. Carpenter.** *Electrical World*, volume 100, November 12, 1932, pages 656–8.

26. Mechanical Design of Bus Bars (in Russian), **A. Zingerman.** *Elektrichestvo* (Leningrad), 2d July, 1932, pages 745–55. Includes a reference list of 20 items.

1933

27. Bolting of Bus-Bar Joints, **E. B. Shand, C. E. Valentine.** *Electric Journal*, volume 30, September 1933, pages 377–80.

28. Channel Slopes Solve Bus Problem, **C. W. Shannon.** *Electrical World*, volume 102, December 2, 1933, page 724.

29. Effect of Bus-Bar Insulation on Heat Dissipation, **R. J. Coe.** *Electrical World*, volume 101, February 18, 1933, pages 223–4.

30. Electrical Contact at Bus-Bar Joints, **C. L. Denault.** *Electric Journal*, volume 30, July 1933, pages 281–3.

31. Electromagnetic Forces on Conductors, **J. W. Bayles, A. Donkin.** *World Power* (London), volume 19, April 1933, pages 216–18.

32. Electromagnetic Forces on Conductors With Bends, Short Lengths, and Crossovers, **C. W. Frick.** *General Electric Review*, volume 36, May 1933, pages 232–4.

33. Engineering Calculation of Inductance and Reactance for Rectangular-Bar Conductors, **O. R. Schurig.** *General Electric Review*, volume 36, May 1933, pages 228–31.

34. Extension of Metal-Clad Units and Flexible-Bus-Support Features of 1932 Switchgear. *Electric Journal*, volume 30, January 1933, page 10.

35. Rapid Solution for Bus-Expansion Problem, **W. B. Morton.** *Electrical World*, volume 102, December 23, 1933, page 825.

1934

36. Avoiding Severe Stresses in Busses, **R. E. Anderson.** *Electrical World*, volume 103, February 24, 1934, pages 287–8.

37. Bus Bars for Outdoor Substations, **A. M. Spruce.** *Engineer* (London), volume 158, December 7, 1934, pages 563–4; December 14, 1934, pages 599–600; December 21, 1934, pages 612–13. Mechanical and electrical design.

38. Flexible Joints in Bus Bars, A. M. Spruce. *Electrical Times* (London), volume 86, September 6, 1934, pages 297–8.

39. New Channel-Bus Design Solves Station Limitations, W. B. Morton, H. L. Unland. *Electrical World*, volume 104, July 7, 1934, pages 18–21. Richmond station of the Philadelphia Electric Company.

40. 7,000-Ampere Station Bus, H. L. Unland, W. B. Morton, V. R. Bacon. AIEE Transactions, volume 53, 1934, June section, pages 994–1004.

41. Stresses in Busses During Short Circuit, and What Can Be Done About It, H. W. Pabst. *Electric Journal*, volume 31, August 1934, pages 322–3.

1935

42. Electrical Design Features of Richmond Station Unit, R. W. Wilbraham, R. Bailey. *Electrical World*, volume 105, August 31, 1935, pages 32–5, 73 (2112–15, 2153).

43. NEMA Power-Switching Equipment Standards. National Electrical Manufacturers Association, New York, N. Y., 1935.

44. Short-Circuit Forces on Bus Bars and Their Supports in Cellular Switchgear, E. E. I. Pilcher. *World Power* (London), volume 24, September 1935, pages 118–23; October 1935, pages 190–2; November 1935, pages 231–5.

1936

45. Copper for Bus-Bar Purposes. Copper Development Association, Publication number 22, London, 1936. 161 pages.

46. Determining Sag in Copper-Tube Bases—Standard Iron-Pipe Sizes, W. S. Scheering. *Electric Journal*, volume 33, October 1936, page 468.

1937

47. Bus Design at Modernized Waterside Features Reliability, A. M. de Bellis. *Electrical World*, volume 108, October 9, 1937, pages 63–6, 138, 141 (1185–8, 1260, 1263).

48. Copper Brazing Lowers Bus-Jointing Cost, R. A. Goeller. *Electrical World*, volume 108, November 6, 1937, pages 64–6, 122, 124 (1530–2, 1588, 1590).

49. Stresses on Conductors; Mechanical Strains Under Short-Circuit Conditions, W. H. Miller. *Electrician* (London), volume 118, April 30, 1937, pages 578–81.

1938

50. Brazing Bus Bars, R. A. Goeller. *Steel*, volume 102, February 21, 1938, pages 50–1, 76.

51. Busses for Welder Loads, L. R. Bogardus. *Electrical Contracting*, volume 37, October 1938, pages 5–7.

52. Contact Problems Associated With the Use of Pure Magnesium for Bus Bars (in German), Walter Bulian. *Elektrotechnische Zeitschrift* (Berlin), volume 59, August 18, 1938, pages 879–81.

53. Cooler Busses With Vents, E. A. Childerhose, H. P. Turner. *Electrical World*, volume 109, February 26, 1938, pages 43, 123 (711, 791).

54. Joining Copper Bus Bars With Brazing Alloys, R. A. Goeller. *Welding Journal*, volume 17, February 1938, pages 26–30.

55. Prebuilt Bus Goes in Quickly, A. E. Bullen. *Electrical West*, volume 80, January 1938, pages 28–9.

56. Reactance of Square Tubular Bus Bars, H. B. Dwight, T. K. Wang. AIEE Transactions, volume 57, 1938, pages 762–5.

1939

57. Erection and Maintenance of Flat and Tubular Bus Bar, L. A. Hunt. *Electrical News* (London), volume 48, July 1, 1939, pages 18–20.

58. J. and P. Switchgear Book, Volume 1, R. T. Lythall. Johnson and Phillips, Ltd. London, 1939, pages 149–64. Bus bars and connections.

59. New Method of Bus Bar Construction in High-Voltage Installation With Specially High Demands (in German), R. Pink. *AEG Mitteilungen*, May 1939, pages 253–6. Briefly describes and illustrates an aluminum bus-bar installation designed to operate at 6 kv and to carry 6,000 amperes at full load with peaks at 200,000 amperes on short circuit.

60. Strength, Capacity in New Bus Design, B. Schrager. *Electrical World*, volume 112, October 7, 1939, page 78 (1054). At Riverside generating station, Northern States Power Company Bus requires fewer supports than are necessary in conventional construction.

1940

61. Double Bus System for Power Transmission, D. I. Bohn, J. E. Housley. *Iron and Steel Engineer*, volume 17, February 1940, pages 26–31.

62. Increase Bus Capacity at South Meadow. *Electrical World*, volume 113, May 4, 1940, pages 50–1 (1356–7).

63. Interlaced Bus Design Solves Space Problem, G. E. Tennant. *Electrical World*, volume 114, October 5, 1940, pages 49–50, 127 (991–2, 1069).

64. Sectionalized Busses, W. M. Hanna. *General Electric Review*, volume 43, October 1940, pages 399–402.

65. Temperature Rise of Bus Bars, H. B. Dwight, G. W. Andrew, H. W. Tileston, Jr. *General Electric Review*, volume 43, May 1940, pages 213–16.

66. 12-Kv Metal-Enclosed Bus and Switch Structure, Station "C," Oakland, Pacific Gas and Electric Company, F. S. Benson, H. E. Strang. AIEE Transactions, volume 59, 1940, pages 751–5.

Section J

Fuses and Fuse Protection

1928

1. Automatic Re-fusing Devices Used on Milwaukee System, O. M. Ward. *Electrical World*, volume 92, November 10, 1928, page 934.

2. Circuit Breakers Eliminated on Rural Circuits, C. S. Fiske. *Electrical World*, volume 92, November 17, 1928, pages 984–5.

3. Critical Study of the Current Rating of Low-Pressure Ordinary-Duty Fusible Cutouts, P. D. Morgan. Institution of Electrical Engineers *Journal* (London), volume 66, September 1928, pages 926–48.

4. E.H.T. Fuses. *Electrician* (London), volume 100, June 22, 1928, page 708.

5. Handy Fuse-Testing Stick. *Electrical World*, volume 92, September 1, 1928, page 404.

6. Hermetically Sealed Cartridge Fuses (in French). A.C.E.C., October–December 1928, pages 180–1.

7. Some Interesting Factors in Fuse Design, G. R. Brown. Hydro-Electric Power Commission of Ontario *Bulletin* (Toronto), volume 15, May 1928, pages 172–5.

8. Tests of Three-Phase Short-Circuiting of Fuses (in Russian), A. Berguer, W. Lookhin. *Elektrichestvo* (Leningrad), October 1928, pages 416–18.

9. Time-Limit Fuses, G. W. Stubbings. *Electrical Review* (London), volume 102, April 27, 1928, pages 727–8.

1929

10. AEG Automatic Push-Button Cutout. *Marine Engineer and Motorship Builder*, volume 52, December 1929, page 480.

11. Application of the Properties of Thin Metal Films to the Manufacture of Delicate Electric Fuses. *Journal of Scientific Instruments*, volume 6, March 1929, pages 102–04.

12. Blowing of Fuses. *Electrical Review* (London), volume 105, November 15, 1929, page 877. "The pressure produced on blowing electric fuse links and striking electric arcs in closed vessels."

13. Checking Time of Operation of Expulsion Fuses, W. Jordan. *Electrical World*, volume 94, October 5, 1929, page 684.

14. Circuit Breaking by Fusible Cutouts and Contactors (in German), C. Paulus. *Elektrotechnische Zeitschrift* (Berlin), volume 50, December 19, 1929, pages 1829–35; December 26, 1929, pages 1875–8. A theoretical and oscillographic examination of the circuit conditions when fusible cutouts and contactors operate through short circuits.

15. Construction, Mode of Operation, and Advantages of the "Tardo" Fuse (in German), E. Junck. *Elektrotechnische Zeitschrift* (Berlin), volume 50, September 19, 1929, pages 1357–9. Illustrated description of a delayed-action fuse for use in circuits where the overloads are only momentary.

16. "ELFA" Push-Button Automatic Cutouts, N. Lanyi. *AEG Progress* (Berlin), volume 5, June-July 1929, pages 232–3.

17. Fuse for Protection Against Excess Current (in German), W. Klement. *Elektrizitaetswirtschaft* (Berlin), volume 28, June 2, 1929, pages 335–42.

18. Fused Arcing Horns and Grading Rings: Design, Construction, and Operating Experience on 66,000-Volt Transmission Lines of the United Gas and Electric Company, Philip Stewart. AIEE Transactions, volume 48, 1929, pages 891–3.

19. Fuses. *Electrical West*, volume 62, May 15, 1929, pages 372–6. Manufacturers' statements and operating company reports.

20. Fuses, Fuse Tubes, Cutouts, and Oil Switches. *Electrical West*, volume 62, May 15, 1929, pages 413–17. Committee report of Pacific Coast Electrical Association.

21. Hatry Fuse. *Electrician* (London), volume 103, October 4, 1929, page 407.

22. Henley Cartridge Fuse. *Electrician* (London), volume 103, November 1, 1929, page 536.

23. High-Voltage High-Power Fuses (in German), W. Estorff. Verband Deutscher Elektrotechniker *Fachberichte* (Berlin), 1929, pages 13–15.

24. Measurement of Switching Voltages by Means of the Cathode-Ray Oscillograph (in German), G. Baust. *Archiv fuer Elektrotechnik* (Berlin), volume 22, July 15, 1929, pages 245–56. Includes tests of fuses.

25. Neutral Reactors Have By-Pass Fuse, H. E. Wulfing. *Electrical World*, volume 93, January 12, 1912, page 95.

26. New Protection System (in German), Eduard Gruenwald. Verband Deutscher Elektrotechniker *Fachberichte* (Berlin), 1929, pages 65–6. Describes a new type of fuse.

27. New System of Slow-Working Fuses (in German), A. Hermanni. *Elektrizitaetswirtschaft* (Berlin), volume 28, February 1, 1929, pages 54–7.

28. Pressure Produced on Blowing Electric Fuse Links and Striking Electric Arcs in Closed Vessels, G. Allsop. *Colliery Guardian* (London), volume 139, August 29, 1929, pages 712–13; also "The Blowing of Fuses," *Electrical Review* (London), volume 105, November 15, 1929, page 877. From Paper No. 52 of the Safety in Mines Research Board, His Majesty's Stationer's Office, London.

29. Shotgun Fuse Solves High-Tension Problem, J. P. Medlin. *Electrical World*, volume 93, February 23, 1929, pages 383–4.

30. 66-Kv Fuse Tests, B. M. Jones, E. H. Coxe. *Electrical World*, volume 93, April 20, 1929, pages 785–6.

31. "Tardo" Fuse (in German), Newmann. *AEG Zeitung* (Berlin), January 1929, pages 4–6.

1930

32. Away With Fuseboards, T. C. Gilbert. *Electrician* (London), volume 105, July 8, 1930, pages 79–81. Points out the hazards and disadvantages of the small and medium-sized fuse as a protective device.

33. Detection of Transient Arcs in Metal-Clad Fusible Cutouts, P. D. Morgan, H. W. Baxter. Institution of Electrical Engineers *Journal* (London), volume 69, December 1930, pages 95–9.

34. Fuse Tester Operates With Transformer and Buzzer, D. Williams. *Power*, volume 72, August 5, 1930, pages 222–3.

35. Fused Grading-Shield Tests, J. E. Clem. *General Electric Review*, volume 33, June 1930, pages 336–40. Tests made on 110-kv line of the Alabama Power Company to determine the performance of high-voltage expulsion-type fuses when used with a grading-shield assembly.

36. Fused Grading Shields, H. A. Frey, E. M. Skipper. AIEE Transactions, volume 49, 1930, pages 990–6.

37. High-Voltage Low-Current Fuses and Switches, Roy Wilkins. AIEE Transactions, volume 49, 1930, pages 96–8.

38. Isolating Switch Fuses. *ASEA Journal* (Västerås, Sweden), volume 7, June-July 1930, pages 102–03.

39. Mathematical Investigation of Fusing, Y. Ikeda, K. Yoneta. Hokkaido Imperial University (Japan) *Engineering Memorandum*, volume 2, December 1930, pages 147–59. "Good agreement with experiment is shown, but the formula is somewhat complicated for practical use."—*Science Abstracts*.

40. Motor Protection (in German), F. Hoppe. *Elektrischer Beitrieb* (Halle, Germany), volume 28, January 15, 1930, pages 1–3; February 20, 1930, pages 16–23. Deals in part with the fuse problem.

41. Protecting 2,300-Volt Motors, B. W. Jones, G. F. Lincks. *Electrical World*, volume 95, January 18, 1930, pages 149–50.

42. Resistors, Rheostats, and Fuses (in Italian), G. Rebora. *Elettrotecnica* (Milan), volume 17, March 5, 1930, pages 149–58. A theoretical study of these three types of devices.

43. Rupturing Characteristics of High-Tension Fuses. *Electrical World*, volume 96, November 8, 1930, pages 870–1. Includes a tabulation of performance data.

44. Testing and Keeping a Record of Fuses, R. Ball. *Power*, volume 71, April 8, 1930, page 561.

45. "Transfuse" Overload Protection, R. W. Biles. *Electrical Review* (London), volume 106, May 2, 1930, pages 820–1.

1931

46. Application of Primary Distribution Fuses (abstract), F. E. Sanford. Electrical Engineering, volume 50, November 1931, page 903.

47. Fuse Cutouts—Their Design and Application for A-C Distribution Circuits (abstract), E. G. Newton. Electrical Engineering, volume 50, November 1931, page 903.

48. Fuse Maintenance, M. Phillips. *Power Plant Engineering*, volume 35, November 15, 1931, page 1105.

49. Fuse Performance in Circuit-Interrupting Service. H. D. Braley. *Power*, volume 74, July 28, 1931, pages 130–3, "The fuse considered in its ability to interrupt a circuit, and the factors that influence its performance in that duty. The results of a series of overload tests made on different size fuses are given."

50. Fuse Performance in Relay Service, H. D. Braley. *Power*, volume 74, August 11, 1931, pages 200–01. Sequel to reference 49.

51. Fuses for High-Power Networks (in German), Eduard Gruenwald. Verband Deutscher Elektrotechniker *Fachberichte* (Berlin), 1931, pages 153–5.

52. High-Power Low-Tension Fuses (in German), H. Besold. Verband Deutscher Elektrotechniker *Fachberichte* (Berlin), 1931, pages 149–52.

53. Mathematical Determination of the Current-Time Curve and of the Limit Current (in German), H. Vollharct. *Elektrotechnische Zeitschrift* (Berlin), volume 52, January 8, 1931, pages 37–40. Applies to the calculation of fuses and other thermal protective devices.

54. Measures for the Safeguarding of Distribution Networks Against the Mounting Short-Circuit Loads of Industrial Concerns (in Dutch), W. Lulofs. *Electrotechniek*, June 24, 1931, pages 186–90. Suggests that manufacturers provide a high-voltage fuse of sufficient interrupting capacity.

55. New Developments in the Construction of Fuses, C. Wehrle. (In German) *AEG Mitteilungen*, October 1931, pages 601–05; (in English) *AEG Progress* (Berlin), volume 8, June 1932, pages 32–5. Illustrated account of the construction and performance of AEG fuses for high capacities.

56. New High-Voltage High-Capacity S.S.W. Fuse, H. Läpple. (In German) *Siemens-Zeitschrift* (Berlin), volume 11, February 1931, pages 65–70; (in English) *Siemens Review* (Berlin), volume 7, number 5, 1931, pages 106–10.

57. Overhead Line Pole Mounting Switch Fuses. *Engineer* (London), volume 152, November 13, 1931, page 526; also "Pole Mounting Switch Fuse," *Engineering* (London), volume 132, December 25, 1931, page 798.

58. Pressures Produced on Blowing Electric Fuse Links (abstract), G. Allsop, P. B. Smith. *Electrical Review* (London), volume 109, July 31, 1931, page 177.

59. Short-Circuit Protection by Fuses (in German), W. Klement. Verband Deutscher Elektrotechniker *Fachberichte* (Berlin), 1931, pages 145–9.

60. "Tedi" Cartridge Fuses (in German), W. Klement. *Siemens Zeitschrift* (Berlin), volume 11, May 1931, pages 229–36. Siemens-Schuckert fuses.

61. Thermal Cutouts for Protecting A-C Motors, H. D. Braley. *Power*, volume 74, November 17, 1931, pages 703–05.

62. Time Lag in Fuses (in Dutch), W. Nobel. *Ingenieur* (Hague), volume 46, September 25, 1931, pages E97-E103. Results of tests to determine the lag of enclosed and open fuses for high currents.

63. Transformer Cutouts, H. J. Crabbs. *Electric Journal*, volume 28, December 1931, pages 673–6. Deals with expulsion-fuse type cutout.

1932

64. Activity at Stafford; A Visit to the English Electric Works. *Electrician* (London), volume 108, April 8, 1932, pages 497–8. Deals in part with fuse manufacture.

65. Adaptation of Circuit-Protective Devices to Load Conditions (in German), W. Zimmermann. *Elektrotechnische Zeitschrift* (Berlin), volume 53, March 10, 1932, pages 237–41; March 24, 1932, pages 289–91. Gives current-time curves for automatic switches and fuse devices with delay characteristics.

66. Application of Primary Distribution Fuses, F. E. Sanford. *Electrical World*, volume 99, April 9, 1932, pages 654–5.

67. Blowing-Time Tests Made on Renewable Fuses. *Power*, volume 75, April 19, 1932, page 583.

68. Boric Acid Eliminates Electrical-Fuse Fireworks. *Scientific American*, volume 147, October 1932, page 233.

69. Boric-Acid Fuse, A. P. Strom, H. L. Rawlins. AIEE Transactions, volume 51, 1932, pages 1020–5.

70. Do Fuses Protect Against Methane Ignitions? A. B. Hooker, E. J. Coggeshall. United States Bureau of Mines *Report of Investigations*, 3179, 1932, pages 1–13.

71. Elements of Switchgear Design (book), F. Kesselring. Pitman, London and New York, 1932. 182 pages. Fuses, page 175.

72. Expulsion Fuse, J. Slepian, C. L. Denault. AIEE Transactions, volume 51, 1932, pages 157–65.

73. Fuse Cutouts, E. G. Newton. *General Electric Review*, volume 35, March 1932, pages 166–72.

74. Fuse Plug for Electrical Circuits. *Engineering* (London), volume 134, December 2, 1932, page 667.

75. Fusing of Voltage Transformers. *Electrical World*, volume 100, July 23, 1932, pages 121–3.

76. High-Voltage Transformer Fuse. *Electrician* (London), volume 109, October 21, 1932, page 518. "Tubular lamp unit; rupturing performance, mechanical vibration at high voltage, and oil-immersion tests." A device constructed by Ferguson, Pailin, Ltd., England.

77. How Fuse Troubles Were Eliminated, L. W. Hayward. *Power Plant Engineering*, volume 36, September 1932, page 673.

78. Impulse Characteristics of Fuse Links, E. M. Duvoisin, T. Brownlee. *General Electric Review*, volume 35, May 1932, pages 260–6.

79. New Fuse Used by the German Federal Railways as a Distribution Fuse for the Electric Heating of Trains (in German), A. Rauch. *Elektrische Bahnen*, volume 8, December 1932, pages 289–91.

80. Noiseless and Flameless High-Voltage Fuse, H. J. Crabbs. *Electric Journal*, volume 29, July 1932, pages 345–7. "A new kind of fuse with a lining of boric acid and with a water-vapor condenser interrupts any arc up to its rating within one half to three cycles with no visible evidence of its operation."

81. Oil Switch Fuse Developments. *Electrical Review* (London), volume 111, November 18, 1932, page 740. "Rotary equipment for 33 kv and a special spring-loaded 'element.'"

82. Protective Devices. *Electrical West*, volume 68, May 15, 1932, pages 431–8. Included fuses. Report of Pacific Coast Electrical Association.

83. Short-Circuit Tests on 132-Kv Fuses. *Engineer* (London), volume 164, October 14, 1932, pages 378–9.

84. Spring-Type Potential Transformer Fuses, A. R. Hand. *General Electric Review*, volume 35, February 1932, pages 113–19. "Improved high-voltage fuse for instrument transformers."

85. Switch Fuses for Overhead Lines. *Engineering* (London), volume 134, September 30, 1932, page 404. Equipment constructed by General Electric Company, Ltd., England.

86. Time-Limit Fuses, G. W. Stubbings. *Electrical Engineer and Merchandiser* (Melbourne), volume 9, November 1932, pages 221–3.

87. Urges Domestic Breakers Supplant Fuses, W. M. Sullivan. *Electrical World*, volume 99, May 21, 1932, pages 907–08.

1933

88. Bakelite Sealing Chambers for Cable Entry. *Electrician* (London), volume 110, February 17, 1933, pages 235–6. A fuse unit of British manufacture.

89. Behavior of Industrial Control Devices Under Short Circuit, B. W. Jones. *General Electric Review*, volume 36, October 1933, pages 441–6. Includes a discussion of fuses.

90. Carbon Tetrachloride or Porcelain Fuses? G. H. Dean. *Electrical Review* (London), volume 112, January 27, 1933, pages 120–1.

91. Comparison of Arc-Extinguishing Power of Various Anhydrous Inorganic Oxides (in Japanese; English abstract), S. Fukuda. Institute of Electrical Engineers, Japan, *Journal* (Tokyo), volume 53, September 1933, pages 729–33. Tests on oxides as fuse filler.

92. Co-ordinating Fuse and Relays for Distribution Reliability, G. F. Lincks. *Electrical World*, volume 102, July 29, 1933, pages 140–3.

93. Film Cutouts, S. B. Kraut. *Electric Journal*, volume 30, September 1933, pages 362–3.

94. Fuse-Link Improvement Gives Co-ordinated Protection, G. F. Lincks. *Electrical World*, volume 102, November 4, 1933, pages 602–04.

95. Fuses, E. S. Savage. *Bell Laboratories Record*, volume 12, September 1933, pages 27–30. On small fuses, such as are used by the Bell System.

96. Fusible Cutouts, F. C. Bryan. *Electrician* (London), volume 110, April 28, 1933, pages 554–6.

97. Hazards of Defective Cords and Fuses, H. M. Naylor. *Safety Engineering*, volume 66, November 1933, page 174.

98. High-Voltage Circuit Breaker and Its Competitor, the High-Voltage Fuse, W. D. D. Fenton. *Electrician* (London), volume 110, April 28, 1933, page 564.

99. High-Voltage Fuses, E. F. Anderson, F. Henkel. Northwest Electric Light and Power Association, Engineering Section, 10th Annual General Meeting, *Proceedings*, April 20–22, 1933, pages 1–15.

100. Iron-Clad Switch and Fuse Gear. *Electrical Review* (London), volume 113, September 1, 1933, page 281.

101. Network Protection and Tests With Simple High-Tension Fuses (in German), P. Altburger. *Elektrizaetswirtschaft* (Berlin), December 31, 1933, pages 544–9.

102. New High-Voltage Transformer Fuse. *Electrical Review* (London), volume 112, January 13, 1933, page 46. A fuse developed by Ferguson, Pailin, Ltd., England.

103. Oil-Blast Fuses. *Electrical Review* (London), volume 112, June 23, 1933, page 901. Short account of their construction and performance.

104. Oil-Blast Fuses. *Engineer* (London), volume 156, July 28, 1933, page 95. A 132-kv fuse constructed by the British Thomson-Houston Company.

105. 132-Kv Oil-Blast BTH Fuse. *Electrician* (London), volume 110, June 9, 1933, pages 745–6; *Electrical World*, volume 102, August 19, 1933, page 231.

106. Outdoor High-Tension Fuses, W. J. John. International Conference on Large High Voltage Electric Systems (CIGRE, Paris), *Compte Rendu des Travaux*, 1933, volume 2, report 54, 23 pages.

107. Recent Developments in the Switchgear and Fuse-Gear Departments. *English Electric Journal*, volume 6, September 1933, page 153–61. Illustrated description of switchgear and fuse equipment built by the English Electric Company, Ltd.

108. Suggestion for Defining the Interrupting Capacity of Large Fuses (in German), E. Heusser. Association Suisse des Electriciens *Bulletin* (Zurich), volume 24, number 25, 1933, pages 656–8.

109. Theory of the Limiting Current in Fuses (in German), J. A. M. van Liempt. *Zeitschrift fuer Physik* (Berlin), volume 86, November 10, 1933, pages 387–91.

110. "Wax-Operated" Switches, A. G. Bullen. *Electrical Review* (London), volume 112, February 3, 1933, pages 152–3. A special type of fuse for small fractional-horsepower motors. A small strip of wax with a copper covering is acted on by the thermal effect of overloads.

1934

111. Automatic Protective Gear for A-C Supply Systems (book), J. Henderson. Pitman, London and New York, 1934. 201 pages. Some material on fuses.

112. Comparison of Arc-Extinguishing Power of Various Organic Compounds and Inorganic Ammonium Salts (in Japanese; English abstract), T. Nishi, S. Fukuda. Institute of Electrical Engineers, Japan *Journal* (Tokyo), volume 54, July 1934, pages 683–8. Tests with fillers for cartridge fuses.

113. Co-operative Use of Motor Protective Switches and Fuses (in German), F. Denk. *Elektrotechnische Zeitschrift* (Berlin), volume 55, November 8, 1934, pages 1093–5.

114. Domestic-Service Fuse Replacements, F. D. Parker. *Electrical Review* (London), volume 114, May 18, 1934, pages 698–9.

115. Economic and Technical Advantages of Use of Heavy-Duty Fuses in Switchgear Installations (in German), E. König. Verband Deutscher Elektrotechniker *Fachberichte* (Berlin), 1934, pages 70–2.

116. Factory Switchgear: The Question of Rating, J. O. Knowles. *Electrical Review* (London), volume 115, July 13, 1934, pages 43–4. Includes a discussion of rupturing capacity of fuses.

117. Fuse Protection Against Reverse Currents in Low-Voltage Networks (in German), P. Wittich. *Elektrotechnik und Maschinenbau* (Vienna), volume 52, December 23, 1934, pages 602–03.

118. Fuses for Low Currents in Measuring Circuits (in German). *Elektrotechnische Zeitschrift* (Berlin), volume 55, April 19, 1934, pages 391–3; April 26, 1934, pages 417–20.

119. Fuses Save Industrial Customer, J. H. Evans. *Electrical World*, volume 104, July 28, 1934, pages 116–17.

120. High-Power Fuses for Distribution Circuits (in Russian), O. B. Bron, I. M. Pesik. *Elektrichestvo* (Leningrad), 1st and 2d July, 1934, pages 41–51. General survey of recent developments, giving some design data.

121. High-Rupturing-Capacity Fuses. *Engineer* (London), volume 158, October 26, 1934, pages 417–19; November 2, 1934, pages 432–4; November 9, 1934, pages 456–7; November 16, 1934, pages 482–4; November 23, 1934, pages 517–19.

146. Littel Antivibration Fuses. *Mass Transportation*, volume 31, April 1935, page 126.

147. Maintenance of Time-Limit Fuses, **H. Hurworth.** *Electrical Review* (London), volume 117, November 8, 1935, page 640.

148. Oil-Immersed Switch Fuse. *Engineer* (London), volume 159, March 29, 1935, page 336.

149. Overload Protective Systems; Fuses. *Electrician* (London), volume 115, October 4, 1935, page 417.

150. Recent Developments in High-Voltage Fuses, **K. A. Lohausen.** (In German) *AEG Mitteilungen*, December 1935, pages 402–04; (in English) *AEG Progress* (Berlin), number 2, 1936, pages 28–9. Illustrated description of AEG fuses.

151. Sectionalizing Fuses With Banked Transformers, **M. M. Koch.** *Electrical World*, volume 105, August 17, 1935, pages 1990–1.

152. Service Tests Made on Fused Cutouts, **R. E. Jones.** *Electrical World*, volume 105, August 31, 1935, page 2142.

153. Tests of Fuse Switches, **R. E. Jones.** Hydro-Electric Power Commission of Ontario *Bulletin* (Toronto), volume 22, January 1935, pages 23–8.

154. Theory of High-Voltage Heavy-Duty Double-Wire Fuses (in French), **O. Szilas.** International Conference on Large High-Voltage Electric Systems (CIGRE, Paris), *Compte Rendu des Travaux*, 1935, volume 3, paper number 345, 13 pages.

155. Time-Limit Fuses, **H. Hurworth.** *Electrical Review* (London), volume 117, October 18, 1935, pages 527–8. Characteristics required to ensure satisfactory service.

156. Time of Melting Fuses (in German), **J. A. M. van Liemp, J. A. de Vriend.** *Zeitschrift fuer Physik* (Berlin), volume 98, November 30, 1935, pages 133–40.

1936

157. Calculation for Distribution Faults, **G. F. Lincks, H. G. Brinton.** *Electrical World*, volume 106, February 1, 1936, pages 334–6.

158. Calorimetry of a Hot Wire (in French), **H. Duclot.** Association des Ingénieurs Electriciens Sortis de l'Institut Electrotechnique Montefiore *Bulletin* (Liege), volume 16, September 1936, pages 204–19, 221–3. Experimental work on fusing of wires.

159. Cressall Manufacturing Company's Field-Discharge Shunt-Break Switch Fuses. *Electrician* (London), volume 117, September 18, 1936, pages 339–40.

160. Davy Mercury-Type Fuse With Plunger. *Electrician* (London), volume 117, October 30, 1936, page 551.

161. Developments in the Electrical Industry During 1935; Fuse Cutouts and Fuse Links, **J. Liston.** *General Electric Review*, volume 39, January 1936, pages 47–8.

162. Experiences and Developments in the Field of High-Voltage High-Capacity Fuses, **H. Läpple.** (In German) *Siemens Zeitschrift* (Berlin), volume 16, March 1936, pages

68–73; (in English) *Siemens Review* (Berlin), volume 4, 1937, pages 128–33. SSW equipment.

163. FULL PROTECTION WITH SIX FUSE SIZES, **J. M. Flanigen.** *Electrical World*, volume 106, October 24, 1936, page 3355.

164. FUSES OF HIGH SHORT-CIRCUIT CAPACITY FOR LOW-TENSION DISTRIBUTION SYSTEMS. *AEG Progress* (Berlin), volume 12, 1936, number 2, page 30.

165. HIGH-RUPTURING-CAPACITY CARTRIDGE FUSE; DESIGN AND APPLICATIONS, **A. M. Pooley.** *English Electric Journal* (London), volume 8, December 1936, pages 93–9. An English Electric Company fuse.

166. LIGHTNING-ARRESTER EXPERIENCE AND PERFORMANCE, **P. B. Hull.** *Electrical West*, volume 77, December 1936, pages 38–41. Includes a discussion of fuse failures.

167. NEW "FORM HA" HIGH-VOLTAGE MEDIUM-CAPACITY FUSES (in German), **K. A. Lohausen.** *AEG Mitteilungen*, volume 12, December 1936, pages 415–20. AEG fuses and their performance.

168. NEW THERMAL FUSE FOR NETWORK PROTECTORS, **L. A. Nettleton.** AIEE TRANSACTIONS, volume 55, 1936 (October section), pages 1096–9; discussion, volume 56, 1937 (August section), pages 1031–3. "By the combination of a fusible alloy of low melting point and copper blocks that delay the rate of temperature rise the fuse described in this paper provides a time-current characteristic which more nearly approaches the ideal."

169. OVERLOAD PERIODS FOR ELECTRICAL EQUIPMENT, **W. Wilson.** *World Power* (London), volume 25, January 1936, pages 8–11; February 1936, pages 84–9; March 1936, pages 138–42. Includes a study of fuse problems.

170. PROTECTION OF ELECTRICAL PLANT; MODERN DEVELOPMENTS (book), **P. F. Stritzl.** Pitman, New York and London, 1936. 200 pages. Fuses, pages 56, 158, 169.

171. PROTECTION OF MOTOR LEADS AGAINST EXCESSIVE HEATING FROM OVERLOAD, **S. Hopferwieser.** *Brown Boveri Review* (Baden), volume 23, November 1936, pages 255–60. Use of fuses and automatic switches.

172. RÉSUMÉ OF REGULATIONS RELATING TO CARTRIDGE FUSES FOR USE IN CIRCUITS UP TO 750 VOLTS, **H. Baxter.** E.R.A. Report, British Electrical and Allied Industries Research Association, London, 1936. 25 pages. Relevant regulations of a number of countries are summarized and compared.

173. SELECTION OF THE INSTANT FOR APPLYING THE VOLTAGE IN THE CASE OF TESTING FUSES BY MEANS OF ALTERNATING CURRENT (in German), **O. Schwenk.** *Elektrotechnische Zeitschrift* (Berlin), volume 57, May 28, 1936, pages 642–3. Uses gas-filled electron tubes.

174. TEST APPARATUS FOR GROUNDED AND GROUNDED-NEUTRAL SYSTEMS (in German), **P. M. Pflier.** *Elektrotechnische Zeitschrift* (Berlin), volume 57, December 3, 1936, pages 1425–6. The apparatus directly indicates the permissible fuse rating.

175. WHERE COLD MOLDING EXCELS; INDICATOR FUSE. *Modern Plastics*, volume 13, June 1936, page 47.

1937

176. ARC EXTINCTION IN GRANULAR EXTINGUISHING MEDIA IN HIGH-TENSION FUSES (in German), **H. Läpple.** *Elektrotechnische Zeitschrift* (Berlin), volume 58, April 8, 1937, pages 369–72, April 22, 1937, pages 426–8.

177. BETTER PROTECTION FOR MOTORS, **J. F. Lincks.** *Electrical World*, volume 108, December 4, 1937, pages 55–6, 134. Advocates the use of the oil fuse cutout.

178. CHARACTERISTICS AND APPLICATIONS OF DELAYED-ACTION FUSES, **W. Klement.** (In German) *Siemens Zeitschrift* (Berlin), volume 17, August 1937, pages 425–31; (in English) *Siemens Review* (Berlin), volume 14, 1938, number 1, pages 12–19.

179. CO-ORDINATION OF FUSE LINKS, **E. M. Adkins.** *Electrical World*, volume 107, March 13, 1937, pages 877, 952. Methods of comparing fuse links and relays for sectionalization and protection.

180. DIFFICULTIES IN CO-ORDINATED FUSING, **J. I. Holbeck.** *Electrical World*, volume 108, November 6, 1937, page 1562.

181. FORMULA FOR THE CURRENT-TIME CURVE OF FUSES AND ITS USE IN THE DETERMINATION OF CHARACTERISTIC VALUES (in German), **H. H. Johann.** *Elektrotechnische Zeitschrift* (Berlin), volume 58, June 24, 1937, pages 684–6.

182. FUSE-BREAKER CORRELATION FIXED BY FAULT RATIO, **P. E. Benner.** *Electrical World*, volume 108, December 18, 1937, pages 2033–4.

183. FUSE PRIMARIES EVEN WHEN USING RECLOSERS, **H. B. Phelps.** *Electrical World*, volume 108, December 4, 1937, page 1872.

184. FUSES OR AUTOMATIC SWITCHES FOR LOW-VOLTAGE INSTALLATIONS (in German), **R. Gasser.** Association Suisse des Electriciens *Bulletin* (Zurich), volume 28, 1937, number 9, pages 177–83. Shows how the two protective devices can be combined to reduce installation and operating expenses.

185. HEARING ELICITS FEW IDEAS ON FUSE-NONTAMPERABILITY. *National Underwriter*, volume 41, October 21, 1937, page 8.

186. HIGH-RUPTURING-CAPACITY HIGH-TENSION FUSES (in French), **R. Besson.** Association Suisse des Electriciens *Bulletin* (Zurich), volume 28, December 10, 1937, pages 656–9.

187. HINTS ON FUSING CONTROL TRANSFORMERS, **K. B. Humphrey.** *Electrical World*, volume 108, December 18, 1937, page 2070.

188. LAYOUT AND RUPTURING CAPACITY OF PROTECTIVE DEVICES IN MOTOR CIRCUITS, **J. O. Knowles.** Institution of Electrical Engineers *Journal* (London), volume 81, August 1937, pages 152–3.

189. NEW HIGH-VOLTAGE HIGH-CAPACITY FUSES, **H. Müller.** *Brown Boveri Review* (Baden), volume 24, September 1937, pages 248–51. Brown Boveri types.

190. OUTDOOR HIGH-VOLTAGE SWITCHGEAR (book), **R. W. Todd, W. H. Thompson.** Pitman, London and New York, 1937. 436 pages. Outdoor high-voltage fuses, pages 342–7.

191. OXIDATION OF FUSIBLE ELEMENTS, **G. N. Nicholson.** *Electrical Review* (London), volume 120, April 2, 1937, page 500.

192. PROPOSED REQUIREMENTS FOR NONTAMPERABILITY OF FUSES. *National Underwriter*, volume 41, December 23, 1937, page 6.

193. PROTECTING HIGH-VOLTAGE MOTORS WITH FUSES, **T. E. Stieber.** *Electric Journal*, volume 34, May 1937, pages 201–04. Construction and application of the boric-acid fuse.

194. PROTECTION OF LIGHTING CIRCUITS IN DWELLINGS (in German), **G. A. Schmidt, H. Schachtner.** *Elektrotechnische Zeitschrift* (Berlin), volume 58, April 22, 1937, pages 421–2. Deals with fuses.

195. RECLOSING FUSES REDUCE OUTAGES ON RURAL LINES 61 PER CENT, **C. C. Cornelius.** *Electric Light and Power*, volume 15, January 1937, pages 32–3. Operating results of 26 months' experience with repeater fuses on rural and semirural distribution lines.

196. REPEATER FUSES, FOUR UNITS IN SERIES, **C. C. Cornelius.** *Electric Light and Power*, volume 15, February 1937, pages 32–3, 35.

197. SHORT-CIRCUIT PROTECTION OF DISTRIBUTION NETWORKS BY THE USE OF LIMITERS, **C. P. Xenis.** AIEE TRANSACTIONS, volume 56, 1937 (September section), pages 1191–6.

198. SKILLFUL DESIGN OF A SMALL ELECTRICAL PRODUCT, **M. Moeller.** *Electrical Manufacturing*, volume 19, March 1937,

pages 72, 74. Design features of a screw-plug fuse having six separate fuse links and a neon indicator lamp.

199. Split Circuits Reduce Fuse Ratings, Blowing, K. B. Humphrey. *Electrical World*, volume 107, January 16, 1937, page 296.

200. Switches and Fuses; Fire Hazards, F. F. Sengstock. *Weekly Underwriter*, volume 136, February 6, 1937, pages 328, 330.

201. Switchgear for Rural Schemes. *Electrical Review* (London), volume 120, March 12, 1937, page 390.

202. Tamperproof Fuses Now Interchangeable. *Electrical World*, volume 107, June 26, 1937, pages 2260–1.

203. Testing Fuses and Resistance Wires (in French), H. Duculot. Association des Ingénieurs Electriciens Sortis de l'Institut Electrotechnique Montefiore *Bulletin* (Liege), volume 17, February 1937, pages 52–4.

204. Time-Current Curves for High-Voltage Fuses, E. A. Williams. *Electrical World*, volume 107, January 30, 1937, pages 398–401. "Two sets of fuse curves will meet most requirements of co-ordination with relays and breakers."

205. Value of Fuses in Domestic Installations, W. Klement. *Siemens Review* (Berlin), volume 13, 1937, number 5, pages 186–97.

206. When Meters Blow, L. J. Fohr, Jr. *Electronics*, volume 10, January 1937, pages 22–3.

207. Wire and Fuse Sizes for Motor Branch Circuits; Data Sheet. *Power*, volume 81, September 1937, page 514.

1938

208. Application of Time-Limit Fuses, J. R. Mortlock. *British Thomson-Houston Activities*, volume 14, September-October 1938, pages 184–9.

209. Behavior of Fuses in the Case of Electric Impulse Stresses (in German), J. Wrana. *Elektrotechnische Zeitschrift* (Berlin), volume 59, January 6, 1938, pages 11–13. Electrical and mechanical behavior of fuses when subjected to electric switching and lightning impulses.

210. Combined Fuse Puller and Tester Makes for Safety, J. A. Honegger. *Factory Management and Maintenance*, volume 96, September 1938, page 98.

211. Criteria of Severity in the Short-Circuit Testing of Fuses, A. W. Metcalf. *BEAMA Journal* (London), volume 43, August 1938, pages 38–43.

212. Delle Fuse. *Electrician* (London), volume 121, September 23, 1938, page 348.

213. Electric Fuses, A. M. Pooley. *English Electric Journal* (London), volume 9, March-April 1938, pages 12–14; July 1938, pages 55–6. Subtitle: "Some observations on BSS 88/1937 and the factors governing the choice of the type of high rupturing capacity of the fuse to be used."

214. Electric-Transmission High-Tension Fuse. *Electrician* (London), volume 120, February 4, 1938, pages 155–6.

215. Electrical Overload Protection Devices; Operating Characteristics and Fields of Application (in German), W. Schrank. *Archiv fuer Waermewirtschaft und Dampfkesselwesen* (Berlin), volume 19, February 1938, pages 51–4. Deals with the characteristics of slow-acting fuses and automatic circuit breakers.

216. Fuse of High Breaking Capacity (in French), J. Grillet. *Revue Générale de l'Electricité* (Paris), volume 43, May 14, 1938, pages 623–37.

217. Graphs Save Days in Fuse Co-ordination, H. S. Lewis. *Electrical World*, volume 110, July 30, 1938, page 277.

218. High-Rupturing-Capacity Cartridge Fuses. *Engineer* (London), volume 166, September 9, 1938, pages 289–90; *Engineering* (London), volume 146, September 23, 1938, page 363; *Electrical Review* (London), volume 123, October 14, 1938, page 547. Line constructed by the General Electric Company, Ltd., England.

219. New AEG High-Tension Fuses. *AEG Progress* (Berlin), number 1, 1938, pages 22–4.

220. New Medium-Capacity High-Voltage Fuses (in German), K. A. Lohausen. *Elektrotechnik und Maschinenbau* (Vienna), volume 56, April 10, 1938, pages 192–6. AEG equipment.

221. New Method of Protection for Communication Systems, E. R. Benda, W. Wild. *Siemens Review* (Berlin), volume 14, 1938, number 3, pages 124–9.

222. New Protective System for Communication Installations (in German), E. R. Benda, W. Wild. *Siemens Zeitschrift* (Berlin), volume 18, May 1938, pages 244–9. Construction and performance of a new Siemens and Halske fuse for lightning protection of telephone lines.

223. New Triple-Pole Switch. *Engineer* (London), volume 166, November 25, 1938, pages 597–8; also "The 'Isofuse' Switch," *Engineering* (London), volume 146, December 2, 1938, page 662. Brookhirst "Isofuse."

224. New Type of Controlled Fuse For Interconnected Networks (in German), H. Muth, K. Zimmermann. *Elektrotechnische Zeitschrift* (Berlin), volume 59, November 24, 1938, pages 1257–62. Heat for melting the fuse is obtained by letting a relay current induce a chemical reaction.

225. New Ways in the Design of High-Capacity Fuses (in German), F. Driescher. *Elektrotechnische Zeitschrift* (Berlin), volume 59, March 10, 1938, pages 264–6.

226. On the Characteristics of High-Voltage Plug-Type Fusible Cutouts (in Japanese), T. Utiyama, R. Arai. Circular number 111, Electrical Laboratory, Tokyo, Japan, 1938, 38 pages.

227. Outdoor Fuse Isolator, *Engineer* (London), volume 165, April 8, 1938, page 402. General Electric Company, Ltd., England.

228. Progress in the Construction of High-Voltage Fuses (in German), K. A. Lohausen. *Elektrotechnische Zeitschrift* (Berlin), volume 59, March 3, 1938, pages 222–5.

229. Protection by Fuses; Matching Fuse Performance to Cable Protection, H. W. Baxter. *Electrician* (London), volume 121, August 12, 1938, pages 173–5. Abridged from Report Ref. G/T101 of the British Electrical and Allied Industries Research Association.

230. Reclosing Fuses Improve Rural-Line Reliability, C. D. Brown. *Electric Light and Power*, volume 16, April 1938, pages 52–3. "Operating experience of the Milwaukee Electric Railway and Light Company, totaling 48 feeder years, shows 1.5 fuse operations per feeder per year."

231. Saving Distribution Transformers From Overloads and Short Circuits, G. W. Westcott. *Electrical West*, volume 80, April 1938, pages 34–5.

232. Single-Phase Switch Fuse. *Engineering* (London), volume 146, September 30, 1938, page 402; also "A High Rupturing Capacity Switch and Fuse Unit". *Engineer* (London), volume 166, October 7, 1938, pages 397–8. Switchgear and Cowans, Ltd.

233. Too Much Diversity in System Fuse Links, E. F. Boothe. *Electrical World*, volume 109, January 29, 1938, pages 408–10, 473, 475. "Fewer sizes, more uniform spacing between ratings, agreement on one curve shape for time-current characteristics will simplify problems of operating engineer and manufacturer." Suggested standards.

234. What Time-Delay for Automatic Reclosure? G. F. Lincks. *Electrical World*, volume 110, December 31, 1938, pages 1822–3. Reclosing fuse cutouts.

1939

235. Application of the High-Rupturing-Capacity Fuse to Industrial Distribution, **H. Simmonds.** *Electrical Times* (London), volume 95, June 8, 1939, pages 867–70.

236. Cartridge Fuses, *Engineer*, volume 167, March 31, 1939, pages 415–16. An English fuse of high rupturing capacity that can be used without changing the associated equipment.

237. Characteristics of Tungsten Fuses (in Japanese), **T. Utiyama, R. Arai.** *Electrotechnical Journal* (Tokyo), volume 3, January 1939, pages 10–13.

238. Current-Limiting Power Fuse, **D. C. Prince, E. A. Williams.** AIEE Transactions, volume 58, 1939 (January section), pages 11–18. Includes a bibliography.

239. Fuse Cutouts Broaden Field of Reclosing Service, **R. S. Bennett.** *General Electric Review*, volume 42, August 1939, pages 357–9.

240. Fuses and Ultrahigh-Speed Circuit Breakers for Direct Current and Alternating Current of Low Voltage (in French), **J. Saint-Germain.** *Revue Générale de l'Electricité* (Paris), volume 46, October 14–21, 1939, pages 381–90. Approximate current value and voltage amplitude which obtains at the moment a fuse blows or a circuit breaker opens.

241. Fuse Blowing Tests, **J. Anderson.** *Electrician* (London), volume 122, January 13, 1939, pages 31–3. "Erratic behavior—danger of open ends."

242. High-Voltage Fuses. *Electrical Review* (London), volume 125, August 18, 1939, page 224.

243. J. and P. Switchgear Book, Volume 1, **R. T. Lythall.** Johnson and Phillips, Ltd., London, 1939. 431 pages. Air break and fuse gear, pages 33–47; switch fuse, page 177; time-limit fuse, page 185; fuse-wire table, page 407.

244. New Fuse Phenomenon, **A. W. Metcalf.** *BEAMA Journal* (London), volume 44, April 1939, pages 109–12. "A globule of solder on a high-conductivity fuse wire dissolves the wire when its own melting point is reached, forming an amalgam of lower conductivity. This is known as the "*M*" effect, and enables the fuse to open on overload at a much lower temperature than a plain wire without the solder bead." Serial.

245. New Model C High-Tension High-Capacity Fuses, **F. Parschalk.** *BBC Nach.*, volume 26, April-June 1939, pages 66–8.

246. Plastics Competition Award to Trico Fuse Manufacturing Company. *Modern Plastics*, volume 17, November 1939, pages 36, 69.

247. Process of Interruption in Circuit Breakers and High-Rupturing-Capacity Fuses Causing no Overvoltage (in French), **A. Gantenbein.** International Conference on Large High-Voltage Electric Systems (CIGRE, Paris), 1939, report 131, 32 pages.

248. Protection of Industrial Motors (in German), **H. Mattel.** *Elektrotechnik und Maschinenbau* (Vienna), volume 57, March 3, 1939, pages 106–11. A discussion of thermal relay as compared with the fuse for protection against overload short circuits.

249. Protective Devices for Telecommunication Purposes, **B. S. Cohen.** Institution of Electrical Engineers *Journal* (London), volume 84, February 1939, pages 237–47. Includes a discussion of fuses.

250. Reclosing Oil Circuit Breakers Versus Repeating Fuses, **R. S. Daniels.** *Electrical West*, volume 83, July 1939, pages 32–4.

251. Switch and Fuse Production, **L. Weekes.** *Electrical Review* (London), volume 124, March 3, 1939, pages 313–14.

252. Testing of Electric Fuses With the Cathode-Ray Oscillograph, **J. A. M. van Liempt, J. A. de Vriend.** *Philips Technical Review* (Eindhoven, Holland), volume 4, April 1939, pages 118–20. "Melting time and short-circuit current can be read off from a single oscillogram."

253. Theory of High-Breaking-Capacity Low-Voltage Fuses (in French), **R. Freiberger.** *Revue Générale de l'Electricité* (Paris), volume 45, April 1, 1939, pages 407–14.

254. Transformer and Line Fusing, **C. H. Hoge.** *Electrical West*, volume 82, June 1939, pages 162–3.

1940

255. High-Rupturing-Capacity Fuses (abstract), **J. W. Gibson.** *Electrician* (London), volume 124, April 26, 1940, page 322.

256. Two-Shot Reclosing Cutouts Improve Farm Line Service, **E. A. Roberts.** *Electric Light and Power*, volume 18, February 1940, page 57.

Bibliography on Electrical Safety 1930–1941

Section A

Electrical Accidents and Their Causes

1930

1. Electric Shock; Interpretation of Field Notes, W. Maclachlan. *Journal of Industrial Hygiene*, volume 12, October 1930, pages 291–9.

2. Low-Voltage Hazards in Industry, R. E. Simpson. *Pulp and Paper Magazine of Canada*, volume 30, December 25, 1930, pages 712–13, 730.

1931

3. Accidents Caused by Electricity (in French), A. Zimmern. Société Française des Electriciens *Bulletin* (Malakoff), volume 1, September 1931, pages 898–937. A review of causes and remedies.

4. High-Voltage Electrical Hazards in Industry. *The Travelers Standard*, volume 19, March 1931, pages 43–8. (Published by The Travelers Insurance Company.)

5. Safety of Those Who Use the So-Called "Low-Voltage" Currents, and the Safety Transformers (in French), M. Rosenfeld. *Revue d'Electricité et de Mecanique* (Paris), May-June 1931, pages 42–6. Advocates use of 30-volt circuits in certain cases.

1932

6. Electrical Accidents in Factories; Report for 1931, H. W. Swann. *Electrician* (London), volume 109, July 29, 1932, page 142.

7. Electricity in Industry, Report of the Inspectors of Factories and Workshops for 1931. *Electrical Review* (London), volume 111, July 1, 1932, page 22.

8. Electricity in Mining; Motors in Use, Accidents Attributable to Power, Exemptions From Regulations, J. A. B. Horsley. *Electrician* (London), October 28, 1932, volume 109, page 557.

9. Fifth International Medical Congress for Industrial Accidents and the Prevention and Treatment of Accidents Due to Electricity. *International Labour Review* (London), volume 25, January 1932, pages 102–03.

10. Responsibility for Electrical Accidents. *Electrical Review* (London), volume 111, December 16, 1932, pages 896–7.

1933

11. Electric Shock and Burns Cause Much Lost Time. *National Safety News*, volume 28, August 1933, page 36.

12. Electrical Accidents, 1932. *Engineer* (London), volume 156, August 25, 1933, page 181.

13. Electricity and Its Safe Use in Everyday Life, A. C. Cramb. *Electrician* (London), volume 110, June 2, 1933, pages 699–700; discussion, page 700.

14. Electricity in Factories. *Electrical Review* (London), volume 113, August 11, 1933, page 186.

15. Electricity Not Dangerous. *Electrical World*, volume 102, October 14, 1933, page 510.

16. Hazards of Defective Cords and Fuses, H. M. Naylor. *Safety Engineering*, volume 66, November 1933, page 174.

17. Liability to Electric Shock, Uzac. *Electrical Review* (London), volume 113, December 1, 1933, page 770.

18. Water-Jet Conductivity. *Electrical Review* (London), volume 113, July 14, 1933, page 48. Conductivity of fire-hose streams.

1934

19. Electrical Accidents—A Study of Recent Statistics, J. B. Harris. *Electrical Review* (London), volume 115, December 7, 1934, page 782.

20. Electrical Injuries: Interpretation of Field Notes—II. Wills Maclachlan. *Journal of Industrial Hygiene*, volume 16, 1934, page 52.

21. Where Low Voltages Are Hazardous, E. W. Gorry. *National Safety News*, volume 29, March 1934, pages 21–2.

1935

22. Electric Shocks From Earthed Apparatus, H. G. Taylor. *World Power* (London), volume 23, April 1935, pages 170–4. Report F/T82 of the British Electrical and Allied Industries Research Association.

23. Facts About Low-Voltage Fatalities, A. Maxwell. Edison Electric Institute *Bulletin*, volume 3, December 1935, page 452.

24. Hazards of Hay Derricks Contacting Electric Lines, G. I. Drennan. *Electrical West*, volume 74, June 1935, pages 146–9.

25. Spraying Water on Electrically Charged Conductors (in German), H. Zaduk. Verein Deutscher Ingenieure *Zeitschrift* (Berlin), volume 79, November 30, 1935, page 1452.

1936

26. Electrical Accidents in Factories. *Engineering* (London), volume 142, August 21, 1936, pages 204–05.

27. Electrical Accidents in Industry, 1935. *Electrical Review* (London), volume 119, July 31, 1936, page 142.

28. Electrical Hazards in Industry, J. V. Peacock. *Safety Engineering*, volume 72, July 1936, page 17.

29. Electricity in Collieries—Causes of Accidents, J. A. B. Horsley. *Electrical Review* (London), volume 119, November 20, 1936, page 708.

30. Static Hazards Met in Solvent Handling, J. T. Morris. *Chemical and Metallurgical Engineering*, volume 43, September 1936, pages 484–5.

1937

31. D-C or A-C? *National Safety News*, volume 35, March 1937, pages 192–3.

32. Electrical Accidents, W. B. Kouwenhoven. AIEE *Transactions*, volume 56, 1937, (September section), pages 1077–8.

33. Electrical Accidents (in French), Uzac. Société Française des Electriciens *Bulletin* (Malakoff), volume 7, November 1937, pages 1165–76.

34. Electrical Accidents in Mines—Abstract of Report for 1936, J. A. B. Horsley. *Engineer* (London), volume 164, September 24, 1937, pages 344–5.

This bibliography on electrical safety was prepared by the AIEE committee on safety and includes a list of the applicable standards, specifications, and safety codes. The items are divided into sections according to subject matter. In sections A, B, D and E the entries are numbered consecutively, subdivided by years beginning with the earliest (1930), and arranged alphabetically by title within each year, the first significant word of the title determining its alphabetical position. In the section on safety standards (C) entries are subdivided according to source. The bibliography was published in pamphlet form by the AIEE during 1942.

35. Electricity in Factories—an Analysis of Accidents and Their Causes, **H. W. Swann.** *Electrical Review* (London), volume 121, October 1, 1937, page 432.

36. Electricity in Factories and Workshops; Chief Inspector's Report for 1936. *Electrical Review* (London), volume 121, July 30, 1937, pages 142–3.

37. High Tension Wires Kill. *Rock Products*, volume 40, August 1937, pages 66–7. Accident in cement plant.

38. Low Voltages Are Not Harmless—Pronounced Hazards May Be Found in Industrial Wiring, **J. Roseveaar.** *National Safety News*, volume 36, July 1937, pages 19–20; (condensed) *Mass Transportation*, volume 33, July 1937, pages 205–06.

1938

39. Electrical Installation Systems and Their Relation to Personal Safety and Fire Risk, **A. L. Whittenham.** *Electrician* (London), volume 121, December 2, 1938, page 662; *Electrical Review* (London), volume 123, December 2, 1938, page 795.

40. Electrical Accidents—Analysis of 1937 Figures. *Electrician* (London), volume 121, November 11, 1938, page 576.

41. Electrical Accidents and Their Causes, **H. W. Swann.** *Engineering* (London), volume 146, December 16, 1938, page 708.

42. Electricity in Factories—Electrical Accidents and Their Causes for 1937, **H. W. Swann.** *Electrical Review* (London), volume 123, November 11, 1938, page 683.

43. Electricity in the Bathroom. *Safety Engineering*, volume 75, June 1938, pages 33–4.

44. Explosive Gas—Electric Spark. *Safety Engineering*, volume 76, July 1938, page 37. Dangerous practice of using unapproved electric portable extension lamps where there are gases or vapors.

45. Housewife Electrocuted. *Safety Engineering*, volume 76 October 1938, page 73. Defective cord.

46. Look Out for "Hot" Wires. *Rock Products*, volume 41, April 1938, page 49.

1939

47. Accident Prevention; Improvement During 1938. *Electrical Review* (London), volume 125, October 20, 1939, pages 523–4.

48. Electricity in Mines; Annual Report of Electrical Inspector of Mines, **J. A. B. Horsley.** *Electrical Review* (London), volume 125, October 20, 1939, page 520.

49. Electricity Intrigues Me, **J. C. Wilson.** *National Safety News*, volume 39, May 1939, pages 32 and 60. Study of electric shock.

50. Fatal Shock From Earthing Plate. *Electrical Review* (London), volume 124, June 9, 1939, page 846.

51. Is the Spray Treatment of Fruit Trees Dangerous When Done in the Vicinity of Overhead Electric Lines? (in French), Association Suisse des Electriciens *Bulletin* (Zurich), volume 30, February 3, 1939, pages 73–5.

52. Lightning Fatalities. *Electrician* (London), volume 123, September 1, 1939, page 246.

53. 110–120; Danger From Defective Electrical Appliances. *Safety Engineering*, volume 78, November 1939, page 24.

1940

54. Electrical Accidents in Switzerland During 1939 (in French), **F. Sibler.** Association Suisse des Electriciens *Bulletin* (Zurich), volume 31, May 31, 1940, pages 249–54.

55. Liability for Accident; Points Raised by a Linesman's Death. *Electrical Review* (London), volume 127, August 2, 1940, page 87.

1941

56. Electric Fence, **C. F. Dalziel, J. R. Burch.** *Agricultural Engineering*, volume 22, November 1941, pages 399–406.

57. "It Must Have Been a Bad Heart," **G. E. Kimball.** *National Safety News*, volume 43, September 1941, pages 81–3. Electrical injuries of so-called low-voltage type.

Section B

Accident Prevention Methods

1930

1. Comparison of the Likelihood of Electrocution on 115/220 Volt A-C Networks With Grounded and Ungrounded Neutral (in French), **G. Burin des Roziers.** *Revue Générale de l'Electricité* (Paris), volume 27, February 22, 1930, pages 296–9.

2. Prevention of Accidents, **T. C. Gilbert.** *Electrical Review* (London), volume 107, November 7, 1930, pages 772–4; November 14, 1930, pages 811–13; November 21, 1930, pages 858–60.

1931

3. Electrical Safety in 132 Pictures (book, in German), **S. Jellinek.** Leipzig, Germany, 1931. 32 pages.

4. Protecting Temporary Workers in Electric Power Stations. *Pulp and Paper Magazine of Canada*, volume 31, March 5, 1931, page 340.

1932

5. How Toledo Edison Cut Accidents 90 Per Cent, **A. Hoefle.** *Electrical World*, volume 99, May 7, 1932, page 826.

6. Promoting Safety by Engineering Design, **A. L. Colligan.** *Electrical World*, volume 99, March 5, 1932, page 462.

7. Safety Control is Like Production Control. **Electrical World**, volume 99, April 23, 1932, page 736.

8. Safety for the Household. National Bureau of Standards, Circular 397, Washington, D. C., 1932. Chapter 5, "Electrical Hazards," pages 50–73.

1933

9. Demonstrating Electric Safety, **E. H. Eitel.** *National Safety News*, volume 28, July 1933, pages 16–18.

10. "Hold Off" Cardholder for Use Near Live Equipment, **F. W. Sulensky.** *Electrical World*, volume 101, March 4, 1933, page 299.

11. Safety Saw for Tree Limbs, **G. F. Harden.** *Electrical World*, volume 101, March 4, 1933, page 294.

1934

12. Curb-Accident Efforts Effective for Ohio Edison. *Electrical World*, volume 103, April 21, 1934, page 577.

13. Design as a Factor in Electrical Accidents. *Engineering* (London), volume 138, December 31, 1934, page 683.

14. Grounding the Neutral of Star-Connected Three-Phase Low-Voltage Networks (in French), **L. Muller.** *Revue Générale de l'Electricité* (Paris), volume 36, September 8, 1934, pages 325–40.

15. Making Manholes Safer by "Remote" Breaker Control. *Electrical World*, volume 103, June 16, 1934, page 872.

16. Potomac Edison Rebuilds a Wood-Pole Line While Still in Service. *Electrical World*, volume 103, June 16, 1934, page 869.

17. Protection Tests Scheduled. *Electrical World*, volume 103, April 28, 1934, page 627. Rubber gloves and boots tested.

18. Steel-Clad Bank for Public Safety, **J. D. Whitaker**, *Electrical World*, volume 103, September 15, 1934, page 423.

1935

19. Accident Prevention in Maintenance Work, **A. C. Sachse.** *Electrical World*, volume 105, December 7, 1935, page 2924.

20. Do Lineman Think? **W. W. Palmer.** *Electric Journal*, volume 32, February 1935, pages 66–8; *National Safety News*, volume 31, May 1935, pages 13–14.

21. Lineman Safety Belt of Woven Fabric. *Electrical World*, volume 105, October 26, 1935, page 2583.

22. Repairs 38-Kv Live Line, **H. L. Talbot.** *Electrical World*, volume 105, March 16, 1935, page 583.

1936

23. Anaesthetic Explosions—Precautionary Measures Necessary With Electrical Apparatus. *Electrician* (London), volume 116, January 17, 1936, page 80.

24. Comparison of Two Methods for Promoting Personal Safety on the Three-Phase Systems; the Insulated and the Grounded Neutral (in French), **L. Castillon.** *Revue Générale de l'Electricité* (Paris), volume 40, July 11, 1936, pages 35–43.

25. Electrocution Through Contact of the Head With a Live Conductor, and an Insulating Helmet for Protection (in French), **A. Dagory.** Société Française des Electriciens *Bulletin* (Malakoff), volume 6, April 1936, pages 433–8.

26. Line Moved "Hot" Quickly at Low Cost, **V. E. Staff.** *Electrical World*, volume 106, September 26, 1936, page 3034.

27. Simple Device Prevents Accidents. *Electrical World*, volume 106, December 5, 1936, page 3796. Door marked to indicate energized equipment.

28. Some Suggestions on the Prevention of Electrical Accidents in Coal Mines, **D. Harrington, C. W. Owings, E. R. Maize.** United States Bureau of Mines. Information Circular 6919, 1936. 14 pages.

29. Static Electricity—Hazards and Safety Measures, **J. M. Myers.** *Power Plant Engineering*, volume 40, October 1936, pages 598–9.

1937

30. Care and Test Extend Rubber Glove Life, **W. L. Garlington.** *Electrical World*, volume 107, May 22, 1937, page 1810.

31. Fence Controls High-Voltage Test Circuit. *Electrical World*, volume 108, October 23, 1937, page 1398.

32. It's Safer If Grounded, **A. F. Edwards, L. A. Hunt.** *Factory Management and Maintenance*, volume 95, January 1937, pages 71–2.

33. Safety Programs Pay Lasting Dividends, **W. E. Mitchell.** *Electrical World*, volume 107, June 5, 1937, page 2005.

34. Temporary Portable Protection Barriers. *Electrical World*, volume 108, December 4, 1937, page 1894.

1938

35. Experience With Protective Measures (in German). Verein Deutscher Ingenieure *Zeitschrift* (Berlin), volume 82, April 30, 1938, pages 533–4.

36. Investigations Into Safety Conditions in Wiring of Buildings With Special Reference to Earth Continuity. **A. J. Levy, H. G. John.** South African Institute of Electrical Engineers *Transactions* (Johannesburg), volume 29, September 1, 1938, pages 223–35.

37. Protect Electricians With Multiple Locks. *Electrical World*, volume 109, February 12, 1938, page 582. Locking tongs protect workmen on "dead" circuit.

1939

38. Warning Barrier for Various Conditions. *Electrical World*, volume 109, January 1, 1938, page 60.

39. Finds "Hot Stick" Work Good Practice, **H. E. Clements.** *Electrical World*, volume 111, May 6, 1939, page 1301.

40. Key "Telephoned" With Cyclometer Lock, **J. E. Goodale.** *Electrical World*, volume 112, August 26, 1939, page 620. Safety device used by Consolidated Edison in its distribution system.

41. New Technique in Glove Testing, **R. W. Chadbourn, W. H. Meade.** *Electrical World*, volume 112, July 15, 1939, pages 174–6.

42. Personal Protective Equipment for Electrical Maintenance Men (abstract), **H. W. Arlin.** *Safety Engineering*, volume 77, May 1939, page 36.

43. Respect Low Voltage, **E. W. Beach.** *Safety Engineering*, volume 77, March 1939, pages 21–4.

44. Shocked, **C. L. Keene.** *Safety Engineering*, volume 77, June 1939, pages 6–8; volume 78, July 1939, pages 26, 28. Discussion of electrical injuries and their prevention.

1940

45. Deadly Extension Cords, **G. E. Kimball.** *Safety Engineering*, volume 79, February 1940, pages 9–10.

46. Eleven-Circuit Structure Moved With Lines Hot, **C. T. Malloy.** *Electrical World*, volume 114, November 2, 1940, pages 1322–3.

47. National Electrical Code Handbook—1940, **A. L. Abbott.** McGraw-Hill Book Company, New York, 1940. 589 pages.

48. 1.3 Million Man-Hours of Safety, **H. R. Kurth.** *Electrical World*, volume 114, December 14, 1940, pages 1781–3.

49. Tower Repaired With Line Hot. **Electrical World**, volume 114, December 14, 1940, page 1806.

1941

50. Control of Kite-Flying Hazards, **G. S. Diehl.** Edison Electric Institute *Bulletin*, volume 9, March 1941, page 105.

51. Demonstrations Hold Attention, **H. G. Pruett, W. A. Keller.** *National Safety News*, volume 44, July 1941, pages 93–4.

52. Double Dead-End Serviced While Hot. *Electrical World*, volume 116, November 1, 1941, page 457.

53. Live-Line Guards for Hot-Line Maintenance, **M. L. Fisher.** *Electrical World*, volume 116, November 15, 1941, page 1573.

54. Live Line Tool Operations Studied. *Electrical World*, volume 116, September 6, 1941, page 748.

55. Precautions Against Electrical Accidents. *Power Plant Engineering*, volume 45, February 1941. pages 80–1.

56. Safeguarding CO_2 Use in Cable Manhole, **J. J. O'Brien.** *Electrical World*, volume 115, March 22, 1941, page 996.

57. Safety Holder for Steel Guy Wire. *Electrical World*, volume 115, February 8, 1941, pages 490, 492.

58. A Safety Program on the Campus, C. W. Beese. *National Safety News*, volume 44, December 1941, pages 12–13, 56+.

59. Take No Chances With Low Voltage. *National Safety News*, volume 44, July 1941, page 54.

60. Twelve Messages on Accident Prevention in the Electric Public Utilities. Booklet C-12, Edison Electric Institute, New York.

Section C

Safety Codes and Standards Aimed at the Prevention of Electrical Accidents

(Note: Codes and Standards are subject to constant revision. The following are based on lists issued up to July 1, 1942; latest lists issued by sponsoring organizations should be consulted for complete accuracy at any time.)

National Electrical Safety Code

(The following may be obtained from the American Standards Association, 29 West 39th Street, New York, N. Y., or from the United States Government Printing Office, Washington, D. C.)

National Electrical Safety Code. Published by the Government Printing Office, Washington, D. C., in six separate parts, as follows:

Part I. Safety Rules for the Installation and Maintenance of Electrical Supply Stations. *C*2.1–1941. National Bureau of Standards Handbook 31.

Part II. Safety Rules for the Installation and Maintenance of Electric Supply and Communication Lines. *C*2.2–1941. National Bureau of Standards Handbook 32.

Part III. Safety Rules for the Installation and Maintenance of Electric Utilization Equipment. *C*2.3–1941. National Bureau of Standards Handbook 33. See also National Electrical Code which covers part of same field.

Part IV. Safety Rules for the Operation of Electric Equipment and Lines. *C*2.4–1939. National Bureau of Standards Handbook 34.

Part V. Safety Rules for Radio Installations. *C*2.5–1940. National Bureau of Standards Handbook 35. Applies to radio transmitting and receiving installations, including antennas, counterpoise wires, lead-in conductors, grounding conductors, grounding connections, protective devices, and batteries; does not apply to portable or mobile installations nor to carrier-current coupling equipment.

Part VI. Safety Rules for Electric Fences. National Bureau of Standards Handbook 36. Rules of construction, performance, and installation of fences and controllers.

National Electrical Code

(The following may be obtained from the National Board of Fire Underwriters, 85 John Street, New York, N. Y.)

National Electrical Code. *C*1–1940. National Board of Fire Underwriters Pamphlet 70. Prepared by the electrical committee of the National Fire Protection Association; published by the National Board of Fire Underwriters. Purpose is the safeguarding of persons and property from the hazards arising from the use of electricity within or on public or private buildings and premises, with certain exceptions. Covers accident as well as fire hazard. Revised periodically. See also National Electrical Safety Code.

Underwriters' Laboratories Publications

(The following standard specifications covering electric devices and materials may be obtained from Underwriters' Laboratories, Inc., 207 East Ohio Street, Chicago, Ill.; 161 Sixth Avenue, New York, N. Y.; 500 Sansome Street, San Francisco, Calif. List corrected to February 21, 1942.)

Air-Conditioning and Commercial Refrigerating Equipment. December 1941.

Arc-Welding Equipment, Transformer-Type. September 1937.

Armored Cable. March 1941.

Attachment Plugs and Receptacles. September 1939.

Cabinets and Boxes. February 1941.

Christmas-Tree and Decorative-Lighting Outfits. May 1941.

Circuit-Breakers, Branch-Circuit and Service. June 1940.

Cleats, Knobs, and Tubes (Porcelain). November 1937.

Conduit (Flexible-Steel). July 1938.

Conduit (Rigid-Steel). November 1935.

Cord Sets. October 1937.

Cutout Bases. April 1934.

Electrode Receptacles for Gas-Tube Signs. February 1940.

Fans (Motor-Operated). March 1938.

Fence Controllers (Electric). September 1937.

Fire-Alarm Cables. April 1941.

Fittings (Electrical) for Use in Hazardous Locations. March 1941.

Fixtures (Electric Lighting) and Portable Lamps. September 1941.

Fixtures (Electric Lighting) for Use in Hazardous Locations. August 1934.

Flatirons and Ironing Machines (Electric). June 1940.

Flexible Cord and Fixture Wire. October 1935.

Fuses. February 1941.

Gas-Tube Sign and Oil-Burner Ignition Cable. January 1936.

Heating Appliances (Electric). May 1940.

Heating Pads (Electric). June 1935.

Industrial Control Equipment. July 1938.

Industrial Control Equipment for Use in Hazardous Locations. March 1941.

Lamp-Holders, Edison-Base. March 1941.

Lighting Plants (Electric). September 1921.

Motor-Operated Appliances. April 1937.

Motors and Generators (Electric) for Use in Atmospheres of Combustible Dust, Class II, Group G. June 1941.

Motors and Generators (Electric) for Use in Hazardous Locations, Class I, Group D. Part I, Integral-Horsepower Motors; Part II, Fractional-Horsepower Motors. June 1941.

Nonmetallic-Sheathed Cable. July 1941.

Outlet Boxes and Fittings. November 1941.

Panelboards. March 1941.

Raceways and Fittings (Surface Metal). December 1940.

Raceways and Fittings (Metallic Underfloor). July 1934.

Raceways and Fittings (Nonmetallic Underfloor). August 1934.

Radio-Receiving Appliances, Power-Operated. April 1938.

Ranges (Domestic Electric). December 1940.

Rectifiers. July 1940.

Refrigerating Systems (Absorption-Type). December 1941.

Refrigerating Systems (Unit). December 1941.

Service Cables. April 1937.

Service Equipment. June 1936.

Signs (Electric). March 1940.

Soldering Lugs. January 1930.

Switchboards (Dead-Front). July 1938.

Switches (Enclosed). June 1936.

Switches (Knife). May 1939.

Switches (Snap). August 1941.

Therapeutic Carbon-Arc Lamps. July 1930.

Time-Indicating and Recording Appliances. October 1941.

Transformers (Specialty). June 1940.

Tubing (Flexible Nonmetallic). September 1939.

Wire Connectors (Pressure). May 1939.

Wires and Cables (Rubber-Covered). June 1940.

Wires and Cables (Varnished-Cloth). November 1939.

Wires (Synthetic-Insulated) (Proposed Requirements). May 1940.

Approved Canadian Standards

(The following Standard Specifications may be obtained from the Canadian Engineering Standards Association, National Research Building, Ottawa, Ont. List is corrected to March 31, 1942.)

Canadian Electrical Code, Part I. Essential Requirements and Minimum Standards Governing Electrical Installations for Buildings, Structures, and Premises. (Inside Wiring Rules) *C*22.1–1939.

Canadian Electrical Code, Part II. Specifications for Construction and Test of Electrical Equipment. (Approval Specifications.) *C*22.2. Includes the following Standard Specifications, which are published separately:

Air-Cooled Transformers (Dry Type). *C*22.2 No. 47–1940.

Armoured Cable and Armoured Cord. *C*22.2 No. 51–1941.

Asbestos-Insulated Wires and Cables. *C*22.2 No. 28–1941.

Automatic Motor-Control Devices of Small Capacity. *C*22.2 No. 24–1935.

Auxiliary Gutters, Junction Boxes, and Pull Boxes. *C*22.2 No. 26–1935.

Cabinets and Cutout Boxes. *C*22.2 No. 20–1936.

Cable for Luminous-Tube Signs and for Oil-Burner Ignition Equipment. *C*22.2 No. 17–1935.

Capacitors (Electrical Condensers). *C*22.2 No. 8–1934. Under revision.

Christmas-Tree and Other Decorative-Lighting Outfits. *C*22.2 No. 37–1937.

Cord Sets (second edition). *C*22.2 No. 21–1941.

Cutout Bases. *C*22.2 No. 39–1936.

Definitions and General Requirements (third edition). *C*22.2 No. 0–1941.

Domestic Electric Clothes Washing Machines. *C*22.2 No. 58–1939.

Electric Air-Heaters. *C*22.2 No. 46–1938.

Electric Clocks. *C*22.2 No. 6–1933.

Electric Cranes and Hoists. *C*22.2 No. 33–1936.

Electric Fixtures (second edition). *C*22.2 No. 9–1941.

Electric Floor-Surfacing and Cleaning Machines. *C*22.2 No. 10–1933.

Electric Portable Lighting Devices (Portables) (second edition). *C*22.2 No. 12–1936.

Electric Ranges. *C*22.2 No. 61–1942.

Electric Signs (second edition). *C*22.2 No. 2–1940.

Electrical Appliances for Hair Dressing and Hand-Drying, Etc. *C*22.2 No. 36–1936.

Electrical Equipment for Measuring and Discharge Devices for Flammable Liquids. *C*22.2 No. 22–1935.

Electrical Equipment for Oil-Burning Apparatus. *C*22.2 No. 3–1933.

Electrically Equipped Machine Tools. *C*22.2 No. 73–1941.

Electrically Heated Warming Pads. *C*22.2 No. 15–1937.

Electrically Operated Refrigerating Machines. *C*22.2 No. 32–1936.

Electrode Receptacles for Luminous-Tube Signs. *C*22.2 No. 34–1936.

Enclosed Branch-Circuit Cutouts. *C*22.2 No. 30–1936.

Enclosed Switches. *C*22.2 No. 4–1935.

Enclosures (Other Than Explosion-Proof) for Use in Hazardous Locations. *C*22.2 No. 25–1936.

Extra-Low-Potential Control-Circuit Wire and Cable. *C*22.2 No. 35–1940.

Flexible Cord and Fixture Wire (second edition). *C*22.2 No. 49–1941.

Flexible Steel Conduit. *C*22.2 No. 56–1938.

Flexible Tubing (Nonmetallic). *C*22.2 No. 44–1937.

Fractional-Horsepower Motors (second edition). *C*22.2 No. 11–1942.

Fuses (Both Plug- and Cartridge-Type). *C*22.2 No. 59–1939.

Ground Clamps. *C*22.2 No. 41–1937.

Industrial Control Equipment for Ordinary Locations (second edition). *C*22.2 No. 14–1942.

Insulated Conductors for Power-Operated Radio Devices. *C*22.2 No. 16–1940.

Integral-Horsepower Electric Motors for Other Than Hazardous Locations. *C*22.2 No. 54–1942.

Isolating Switches. *C*22.2 No. 58–1941.

Knife Switches. *C*22.2 No. 50–1938.

Lamp-Holders Having Socket Screw Shells. *C*22.2 No. 43–1937.

Motor-Operated Appliances, Domestic and Commercial (Fractional Horsepower). *C*22.2 No. 68–1942.

Motor-Operated Blowers and Stokers. *C*22.2 No. 20–1935. Under revision; out of print.

Nonmetallic Sheathed Cable. *C*22.2 No. 48–1938.

Outlet Boxes. *C*22.2 No. 18–1934.

Panelboards. *C*22.2 No. 29–1936.

Porcelain Cleats, Knobs, and Tubes. *C*22.2 No. 69–1940.

Portable Electric Displays and Incandescent-Lamp Signs (second edition). *C*22.2 No. 7–1938.

Portable Electric Vacuum Cleaners. *C*22.2 No. 67–1942.

Power-Operated Radio Devices, Inductively Coupled (Transformer) Type (second edition). *C*22.2 No. 1(A)–1940.

Power-Operated Radio Devices, Conductively Coupled (Transformerless) Type (second edition). *C*22.2 No. 1(B)–1941.

Pull-Off Plugs for Electrothermal Appliances. C22.2 No. 57–1940.

Receptacles, Plugs, and Similar Wiring Devices (second edition). C22.2 No. 42–1942.

Rigid Steel Conduit. C22.2 No. 45–1938.

Rubber-Covered Wires and Cables. C22.2 No. 38–1938.

Service-Entrance and Branch-Circuit Breakers (second edition). C22.2 No. 5–1942.

Service-Entrance Cables. C22.2 No. 52–1941.

Snap Switches. C22.2 No. 55–1942.

Soldering Lugs. C22.2 No. 19–1935.

Specialty Transformers. C22.2 66–1942.

Switchboards. C22.2 No. 31–1939.

Transformers for Luminous-Tube Signs and Oil-Burner Ignition Equipment. C22.2 No. 13–1935.

Wireways and Busways. C22.2 No. 27–1936.

Approved American Standards

(The following may be obtained from the American Standards Association, 29 West 39th Street, New York, N. Y. List corrected to July 1, 1942.)

Accident Prevention in Construction, Manual of. A10.1–1939. Prepared by accident-prevention committee, Associated General Contractors of America, Inc. Contains some references to temporary electrical installations used in construction work.

Coal-Mine Transportation, Safety Code for. M15–1931. Some references to electrical installations.

Compiling Industrial Accident Causes, Recommended Practice for. Z16.2–1941. Part 1, Selection of Accident Factors; Part 2, Detailed Classification of Accident Factors.

Elevators, Dumbwaiters, and Escalators, Safety Code for. A17.1–1937. Also Supplement A17.3–1942. Includes many rules covering special features of the electric equipment peculiar to this application.

Industrial Accident-Prevention Signs, Specifications for. Z35.1–1941. Includes electric warning signs.

Industrial Injury Rates, Method of Compiling. Z16.1–1937.

Industrial Lighting, Recommended Practice for. A11–1942. Includes proper illumination for safety of workers, adequate wiring, exit and emergency lights.

Installation of Blower and Exhaust Systems for Dust, Stock, and Vapor Removal, Regulations for. Z33.1–1938. National Board of Fire Underwriters Pamphlet 91. Mostly about nonelectrical matters, but contains certain important electrical references.

Installing and Using Electrical Equipment in Coal Mines, Safety Rules for. M2–1926. Supplementary to National Electrical Code and National Electrical Safety Code, which cover aboveground installations. Out of print.

Installing and Using Electrical Equipment in Metal Mines, Safety Rules for. M24–1932. Presents recommended practices to minimize hazards in installing and operating electric equipment in underground mining work.

Laundry Machinery and Operations, Safety Code for. Z8–1941. United States Bureau of Labor Statistics Bulletin 375. Imposes certain restrictions on the electric installation.

Lightning, Code for Protection Against. Three Standards, published in one pamphlet: Part I, Protection of Persons, C5.1–1937; Part II, Protection of Buildings and Miscellaneous Property, C5.2–1937; Part III, Protection of Structures Containing Inflammable Liquids and Gases, C5.3–1937. National Bureau of Standards Handbook 21.

Logging and Sawmill Safety Code. B13–1924. Contains some special restrictions on wiring and electric equipment around lumber-handling machinery. National Bureau of Standards Handbook 5. Under revision; out of print.

Mechanical Refrigeration, Safety Code for. B9–1939. Contains certain limits on the use of electric equipment. American Society of Refrigerating Engineers Circular 15.

National Fire Codes for the Prevention of Dust Explosions. Sponsored by the National Fire Protection Association and the United States Department of Agriculture. Eleven Standards, published in one pamphlet, containing rules for structures and processes, ventilation, electric equipment, wiring, removal of dust, and other considerations, in various industries, as follows: Aluminum Bronze Powder, Z12.11–1940; Coal Pneumatic Cleaning Plants, Z12.7–1940; Flour and Feed Mills, Z12.3–1940; Pulverized Fuel Systems, Z12.1–1940; Spice-Grinding Plants, Z12.9–1940; Starch Factories, Z12.2–1940; Sugar and Cocoa, Z12.6–1940; Terminal Grain Elevators, Z12.4–1940; Wood Flour Manufacturing, Z12.8–1940; Woodworking Plants, Z12.5–1940; Inert Gas for Fire and Explosion Prevention, Z12.10–1940.

Paper and Pulp Mills, Safety Code for. P1–1936. Refers to electrical restrictions and to the National Electrical and National Electrical Safety Codes.

Power Presses and Foot and Hand Presses, Safety Code for. B11–1937. Includes special rules covering lighting, means of disconnecting electric power, and switches and other electric apparatus for this application.

Protection of Heads, Eyes, and Respiratory Organs. Z2–1938. National Bureau of Standards Handbook 24. Refers to a few electrical hazards, especially protection of eyes against glare from arcs and electric furnaces.

Protection of Industrial Workers in Foundries, Safety Code for. B8–1932. Includes electrical hazards, such as glare from electric furnaces.

School Lighting, Standards of. A23–1938. Establishes standards of illumination for safety and conservation of vision.

Woodworking Plants, Safety Code for. O1–1930. United States Bureau of Labor Statistics Bulletin 519. Includes a few references to electric equipment.

National Safety Council Safe Practice Pamphlets

(The following may be obtained from the National Safety Council, 20 North Wacker Drive, Chicago, Ill.)

Electric Equipment in Industrial Plants. 29.

Electric Welding Safe Practice. 105.

Portable Electric Hand Tools. 76.

Static Electricity. 52.

Section D

Effects of Electric Shock—Influences of Current, Voltage, Frequency

1930

1. Effects of Electric Shock, W. B. Kouwenhoven, O. R. Langworthy. AIEE *Transactions*, volume 49, 1930, pages 381–94; volume 50, 1931, pages 1165–70.

2. Experimental Study of Abnormalities Produced in the Organism by Electricity, **O. R. Langworthy, W. B. Kouwenhoven.** *Journal of Industrial Hygiene*, February 1930, volume 12, pages 31–65.

3. Resistance of the Human Body to High-Frequency Electric Currents (in German), **N. N. Malov, S. N. Rschevkin.** *Zeitschrift fuer Hochfrequenztechnik* (Leipzig), volume 35, May 1930, pages 177–191.

4. Some Aspects of Electric Shock, **C. L. Kasson.** *Electric Light and Power*, volume 8, March 1930, pages 68–9, 72.

5. Studies of Ventricular Fibrillation Caused by Electric Shock, **Carl J. Wiggers.** Part I, *American Journal of Physiology*, volume 92, 1930, page 223; part II, *American Heart Journal*, volume 5, 1930, page 351; part III, *American Journal of Physiology*, volume 93, 1930, page 197.

1931

6. Considerations Other Than Resuscitation Technique Relating to Electrical Shock—I, **K. K. Berlyn.** *Electric Light and Power*, volume 9, March 1931, pages 28–30.

7. Electric Shock, **W. B. Kouwenhoven.** *Engineers and Engineering*, volume 48, June 1931, pages 137–40.

8. How Low and High Voltages Affect the Body, **J. Russell, Jr.** *National Safety News*, volume 24, July 1931, pages 78–9.

9. Importance of the Points of Contact in Electric Injuries, **O. R. Langworthy, W. B. Kouwenhoven.** *Journal of Industrial Hygiene*, volume 13, May 1931, pages 145–56.

10. Injuries Produced by Surge Discharges, **W. B. Kouwenhoven O. R. Langworthy.** *Electric Journal*, volume 28, August 1931, pages 472–3.

11. Injuries Produced in the Organism by the Discharge From an Impulse Generator, **O. R. Langworthy, W. B. Kouwenhoven.** *Journal of Industrial Hygiene*, volume 13, November 1931, pages 326–30.

12. Nerve Injuries From Electric Shock, **W. B. Kouwenhoven, O. R. Langworthy.** *Electrical Engineering*, volume 50, December 1931, pages 929–32.

13. Physiological Harm and Apparent Death Caused by Electricity, and New Duties of Doctor and Electrical Engineer (in French), **S. Jellinek.** Société Française des Electriciens *Bulletin* (Malakoff), volume 1, July 1931, pages 662–72.

14. Safe Voltages of Electric Currents (in French), **Feraud.** Société Française des Electriciens *Bulletin* (Malakoff), volume 1, March 1931, pages 288–305.

15. Sensitiveness of the Human Body to Feeble Alternating Currents (in German), **E. Albert-Schonberg.** *Elektrotechnische Zeitschrift* (Berlin), volume 52, October 1, 1931, pages 1249–50.

16. What Are the Effects of Electric Shock? **W. B. Kouwenhoven, O. R. Langworthy.** *Electrical Engineering*, volume 50, June 1931, pages 406–10.

1932

17. Cattle and Electric Shocks, **T. C. Gilbert.** *Electrician* (London), volume 108, April 29, 1932, pages 596–8.

18. Electrical Accidents, **S. Jellinek.** *Electrician* (London), volume 109, September 30, 1932, page 403.

19. Electrical Accidents (in French), **S. Jellinek.** International Electrical Congress (Paris) *Comptes Rendus*, volume 8, 1932, pages 307–20. Electropathology.

20. Factors in the Production of Nervous Lesions Following Electric Shocks, **O. R. Langworthy.** *Journal of Industrial Hygiene*, volume 14, March 1932, pages 87–94.

21. Further Research in Injuries From Electric Shock, **W. B. Kouwenhoven, O. R. Langworthy.** *Electrical Engineering*, volume 51, October 1932, pages 693–6.

22. Heart Injury From Electric Shock, **W. B. Kouwenhoven, D. R. Hooker, O. R. Langworthy.** *Electrical Engineering*, volume 51, April 1932, pages 242–4.

23. Necrosis of the Spinal Cord Produced by Electrical Injuries, **Orthello R. Langworthy.** Johns Hopkins Hospital *Bulletin*, volume 51, 1932, page 210.

24. Physiologic Effects Caused by Contact With Electric Circuits (in French), **W. B. Kouwenhoven, O. R. Langworthy.** International Electrical Congress (Paris), *Proceedings*, volume 8, 1932, pages 321–48. Includes bibliography.

25. Reactions of the Organism to Repeated Electric Shocks, **O. R. Langworthy, W. B. Kouwenhoven.** *Journal of Industrial Hygiene*, volume 14, May 1932, pages 197–205.

1933

26. Comment on the Problem of Resistance of Body Against High Frequency (in German), **N. N. Malov.** *Hochfrequenztechnik und Elektroakustik* (Leipzig), volume 41, April 1933, pages 138–41.

27. Electrocution—Notes on the Mechanism of Electric Death, **H. H. U. Cross.** *Electrician* (London), volume 110, May 26, 1933, pages 677–8.

28. Injuries Produced by Contact With Electric Circuits; Experimental Investigations at the Johns Hopkins University, **W. B. Kouwenhoven, O. R. Langworthy.** Franklin Institute *Journal*, volume 215, January 1933, pages 1–26.

29. Method for the Investigation of the Impedance of the Human Body to an Alternating Current, **M. A. B. Brazier.** Institution of Electrical Engineers *Journal* (London), volume 73, August 1933, pages 204–09.

30. Prevention of Electrocution Accidents on the Midi Railway; Tests to Determine the Susceptibility of Personnel to Electrical Accidents (in French), **Uzac.** Société Française des Electriciens *Bulletin* (Malakoff), volume 3, September 1933, pages 930–44.

31. Shock Threshold Fixes Appliance Insulation Resistance, **G. Thompson.** *Electrical World*, volume 101, June 17, 1933, pages 793–5.

32. Study of Injuries Due to Electric Shock and Burns, **H. K. Cook.** *Safety Engineering*, volume 65, March 1933, pages 93–4.

1934

33. Certain Physiological Effects of Alternating Current at Industrial Frequencies (in French), **E. Uytborek.** Société Belge des Electriciens *Bulletin* (Marcinelle), volume 50, April 1934, pages 168–71.

34. Effect of Weak Current Impulses on Human Beings (in German), **W. Koch, H. Maass.** *Wissenschaftliche Veroeffentlichungen aus dem Siemens-Konzern* (Berlin), volume 13, part 3, 1934, pages 63–74. Includes bibliography.

35. Electrocution (in German), **S. Koeppen.** *Eletrotechnische Zeitschrift* (Berlin), volume 55, August 23, 1934, pages 835–7. An investigation of the physiological effects.

36. Experiments in Fatal Electric Shock, **A. G. Conrad, H. W. Haggard.** AIEE *Transactions*, volume 53, 1934, March section, pages 399–402.

37. Experiments Relating to Hazardous Current Intensities and to the Minimum Resistance of the Human Body (in French), **H. Ourson.** *Revue Générale de l'Electricité* (Paris), volume 35, June 9, 1934, pages 779–84.

1935

38. How Electric Shock Affects the Body, **W. B. Kouwenhoven.**

National Safety News, volume 31, February 1935, pages 21–2, 56–7. Bibliography.

1936

39. Action of Electric Shock on the Nervous System (abstract), **L. Marchand, J. Picard.** *Journal of Industrial Hygiene*, volume 18, December 1936, pages 185–6.

40. Body Resistance—Variations With Different Persons and Conditions, **T. C. Gilbert.** *Electrical Review* (London), volume 119, October 2, 1936, pages 435–6.

41. Cattle and Electric Shock, **O. I. Butler.** *Electrical Review* (London), volume 119, November 6, 1936, page 630.

42. Cause of Deaths by Low-Voltage Electric Shocks. *Science*, volume 83, May 15, 1936, page 9.

43. Effect of Electric Shock on the Heart, **L. P. Ferris, B. G. King, P. W. Spence, H. B. Williams.** AIEE *Transactions*, volume 55, 1936, May section, pages 498–515; discussion, page 1264. Includes bibliography.

44. Electric Shock Effects of Frequency, **W. B. Kouwenhoven, D. R. Hooker, E. L. Lotz.** AIEE *Transactions*, volume 55, 1936 April section, pages 384–6.

45. What Is a Safe Voltage? Tests With Current From Hand to Hand, **T. C. Gilbert.** *Electrical Review* (London), volume 119, July 31, 1936, pages 145–6.

1937

46. Electric Shock—Physiological Effects and Resuscitation Methods, **S. W. Fisher, G. M. Harvey.** *Electrical Review* (London), volume 120, April 9, 1937, pages 537–8.

47. Experimental Determination of the Voltage Limit of Harmless Alternating Potentials (in French), **L. Kervran.** *Revue Générale de l'Electricité* (Paris), volume 41, June 5, 1937, pages 723–8.

48. Harmlessness of Alternating Potentials Below 65 Volts (in French), **L. Kervran.** *Revue Générale de l'Electricité* (Paris) volume 42, December 4, 1937, pages 728–31.

1938

49. Anatomo-Pathological Changes Seen After Electric Accidents (abstract), **F. Pietrusky.** *Journal of Industrial Hygiene*, volume 20, May 1938, pages 110–12.

50. Clinical and Neuropathological Aspects of Electrical Injuries, **L. Alexander.** *Journal of Industrial Hygiene*, volume 20, March 1938, pages 191–243.

51. Danger of Electric Shock, **C. F. Dalziel.** *Electrical West*, volume 80, April 1938, pages 30–1.

52. Effect of Electricity on Organisms (in German), **A. K. Kruger.** Verein Deutscher Ingenieure *Zeitschrift* (Berlin), volume 82, March 19, 1938, pages 344–6.

1940

53. Effects of Electric Shock, **S. W. Fisher, G. M. Harvey.** *Electrical Review* (London), volume 126, March 15, 1940, pages 314–15.

54. E.R.A. Reports on Safety in Rural Areas; Sensitivity of Animals to Electric Shock. *Electrician* (London), volume 124, March 15, 1940, page 205.

55. Heat for Shock Treatment. *Electrical Review* (London), volume 128, December 13, 1940, page 135.

56. Some New Ideas Concerning Electrocution (in French), **L. Robida.** *Technique Moderne* (Paris), volume 32, March 1–15, 1940, pages 75–7.

1941

57. Electric Shock, **C. F. Dalziel, J. B. Lagen, J. L. Thurston.** AIEE *Transactions*, volume 60, 1941, pages 1073–8; discussion, pages 1295–7.

58. Electric Shock, Electric Burns, and Their Treatment, **A. E. Gordin.** *Industrial Medicine*, volume 10, March 1941, pages 87–91.

59. Practical Aspects of Electric Shock, **C. F. Dalziel, J. B. Lagen.** *Electrical West*, volume 86, March 1941, pages 40–5.

Section E

Resuscitation—Methods, Apparatus, Results

Before 1930

1. A Manual of Artificial Respiration (book), **G. R. G. Fisher.** Stratford Company, Boston, 1923. 80 pages.

2. Noxious Gases and the Principles of Respiration Influencing Their Action (book), **Yandell Henderson, Howard W. Haggard.** Chemical Catalog Company, New York, 1927. 220 pages.

3. The Problem of Resuscitation From Electrical and Other Accidents in the United States and Canada (pamphlet), **C. K. Drinker.** 1928. 31 pages.

1930

4. Report of the AGA Subcommittee on Promotion of the Use of the Schafer Prone Pressure Method of Resuscitation. American Gas Association *Proceedings*, 1930, pages 75–8.

1931

5. Doctor Explains the Prone Pressure Method, **R. H. Ferguson.** *National Safety News*, volume 23, June 1931, pages 17–18.

6. Electrical Accidents and First Aid Practices (in French), **R. Legendre.** Société Française des Electriciens *Bulletin* (Malakoff), volume 1, October 1931, pages 1091–104.

7. Using Vital Moments in Life Saving, **W. M. Holtz.** *Safety Engineering*, volume 62, December 1931, pages 361–2; *National Safety News*, volume 25, January 1932, pages 20–1; National Electric Light Association *Bulletin*, volume 19, April 1932, pages 228–9.

1932

8. Insull Medal—The First Ten Years, **W. Maclachlan.** National Electric Light Association *Bulletin*, volume 19, July 1932, page 431.

9. Is Our Prone-Pressure Teaching Effective? **R. Clair.** *National Safety News*, volume 25, June 1932, pages 21–2, 62.

10. Prone Pressure Succeeds in Remarkable Case. *Safety Engineering*, volume 64, July 1932, page 36.

11. Resuscitation, **F. E. Shipway.** American Gas Association *Monthly*, volume 14, January 1932, page 15.

12. Surgeon's Message to Utilities, **S. R. Benedict.** *Electrical World*, volume 99, January 16, 1932, pages 140–1.

1933

13. Resuscitation by Countershock, **W. B. Kouwenhoven, R. D. Hooker.** *Electrical Engineering*, volume 52, July 1933, pages 475–7.

14. How Efficient Are Respirators? **R. C. Stratton.** *National Safety News*, volume 27, February 1933, pages 21–2.

1934

15. Rocking Method of Artificial Respiration, **H. W. Gentles.** *National Safety News*, volume 29, April, 1934, page 38.

1935

16. Cheating Death Through Resuscitation, **T. Burke.** *National Safety News*, volume 32, July 1935, page 20.

17. Emergency Practices in Resuscitation (letter), **J. M. Buswell.** *Electrical Engineering*, volume 54, August 1935, pages 909–10.

18. Holger Nielsen Method of Resuscitation, **W. Maclachlan.** *National Safety News*, volume 32, September 1935, page 52. Compared with the Schafer method.

19. McCarter Medals Awarded for Life Saving. American Gas Association *Monthly*, volume 17, December 1935, pages 454–5.

20. Modification of the Nielsen Method of Artificial Respiration, **C. K. Drinker, L. A. Shaw.** *Journal of Industrial Hygiene*, volume 17, November 1935, pages 243–6.

21. New Method of Artificial Respiration, **H. W. Gentles.** *National Safety News*, volume 32, August 1935, page 34. Holger Nielsen method.

22. Sir Edward Schafer and His Contribution to Life Saving. *National Safety News*, volume 32, October 1935, page 50.

23. Tilting for Resuscitation. *Scientific American*, volume 152, January 1935, page 33.

24. Twelve Recent Awards of Edison Electric Institute Medal. Edison Electric Institute *Bulletin*, volume 3, February 1935, pages 48–50.

25. Twelve Years' Experience in the Effective Administration of Resuscitation, **C. K. Drinker.** American Gas Association *Proceedings*, 1935, pages 13–18.

1936

26. Annual Contest Brings Improvement in Prone Pressure Application, **J. M. Connolly.** American Gas Association *Monthly*, volume 18, December 1936, pages 429–30.

27. New Device for Resuscitation Training, **W. C. Grant.** American Gas Association *Monthly*, volume 18, September 1936, pages 299–301. Designed and built by C. I. Langdon.

28. New Device Standardizes Life-Saving Technique. *Industrial Standardization*, volume 7, November 1936, pages 290–1. C. I. Langdon's device.

29. Resuscitation by the Prone-Pressure Method; Directions. Edison Electric Institute *Bulletin*, volume 4, April 1936, page 154.

30. Resuscitation from Electrical Shock, **W. Maclachlan.** Edison Electric Institute *Bulletin*, volume 4, January 1936, page 22.

31. Resuscitation With Carbon Dioxide, **Y. Henderson.** *Science*, volume 83, May 1, 1936, pages 399–402.

32. Surer Artificial Respiration—Nielsen Life-Saving Technique Surpasses, by 41 Per Cent, the Widely Used Schafer System, **F. D. McHugh.** *Scientific American*, volume 154, January 1936, page 17.

33. Ten Recent Awards of Edison Electric Institute Medals. Edison Electric Institute *Bulletin*, volume 4, February 1936, pages 58–60.

34. They Turned Back Death. *National Safety News*, volume 34, December 1936, page 27. President's Medal awards for life-saving by the prone-pressure method.

1937

35. Miracle Men, **C. F. Scheer.** *National Safety News*, volume 36, October 1937, pages 71–2. Prone-pressure method.

36. Seventeen Recent Awards of Edison Electric Institute Medals. Edison Electric Institute *Bulletin*, volume 5, February 1937, pages 51–5.

37. What Are the Prospects for Success With Artificial Respiration in Cases of Electric Shock? (in French). Association Suisse des Electriciens *Bulletin* (Zurich), volume 28, November 12, 1937, pages 597–8.

1938

38. Adventures in Respiration (book), **Yandell Henderson.** Williams and Wilkins Company, Baltimore, 1938. 316 pages.

39. Apparatus for Artificial Respiration (in French). *Genie Civil* (Paris), volume 112, April 23, 1938, pages 356–7.

40. Comparison of Pulmonary Ventilation in Three Methods of Artificial Respiration, **B. G. King** and others. *Journal of Industrial Hygiene*, volume 20, November 1938, pages 576–80.

41. Injuries From Artificial Respiration, **H. E. Fisher.** *Concrete* (Mill Section), volume 46, July 1938, page 212.

42. Mechanical Resuscitation in Advance Forms of Asphyxia; A Clinical and Experimental Study in the Different Methods of Resuscitation, **P. N. Coryllos.** *Journal of Industrial Hygiene*, volume 20, November 1938, pages 191–2 (supplement).

43. The Use and Care of Respirators. Air Hygiene Foundation of America, Inc., Pittsburgh, 1938. 7 pages. Includes list of respiratory protective devices approved by the United States Bureau of Mines. Preventive Engineering series.

1939

51. Breathing Machines and Their Use in Treatment. Great Britain Medical Research Council, London, 1940, 90 pages.

52. Care of Respirators. *Safety Engineering*, volume 79, February 1940, page 25.

53. Control of Respiration Under Artificial Respiration, **Y. Henderson.** *Science*, volume 91, May 3, 1940, page 422.

54. Improving Performance of Artificial Respiration, **H. G. Hays.** *National Safety News*, volume 42, September 1940, pages 22–3.

55. Just a Human Guinea Pig. *National Safety News*, volume 41, June 1940, page 81. Results of respirator tests.

56. Manual of First Aid Instructions. United States Bureau of Mines, 1940, 361 pages.

57. Pole-Top Resuscitation—Its Place in the Training Program, **W. R. Smith.** Edison Electric Institute *Bulletin*, volume 8, November 1940, pages 507–08; *National Safety News*, volume 43, February 1941, pages 24–5.

58. Resuscitation From Shock, **S. Jellinek.** *Electrical Review* (London), volume 126, January 5, 1940, pages 10–11; discussion giving comparison of methods, **G. H. Bell, J. C. Knox,** volume 127, September 20, 1940, page 241.

59. Resuscitation Performance; How Effective? Tests of Employees in Their Prone-Pressure Application, **H. G. Hays.** *Electrical World*, volume 114, September 7, 1940, pages 681–2.

60. Resuscitation Review Board Is Appointed. EEI Accident Prevention Committee. Edison Electric Institute *Bulletin*, volume 8, May 1940, pages 234+; July 1940, pages 372–3.

61. What to Look for in Respirators, **W. H. Lehmberg.** *Safety Engineering*, volume 79, January 1940, page 30.

62. Wins Medal and Eight Bars. *National Safety News*, volume 42, July 1940, page 19. Saved nine lives by resuscitation.

1941

63. Comparative Physiology of Respiratory Mechanisms (book), **A. Krogh.** University of Pennsylvania Press, Pittsburgh, 1941, 172 pages.

64. Comparison of the Relative Efficiency of the Schafer and Pole-Top Methods of Artificial Respiration, **W. B. Kouwenhoven, D. R. Hooker, O. R. Langworthy.** AIEE *Transactions*, volume 60, 1941, February section, pages 41–4.

65. Resuscitation After Electric Shock, **C. F. Dalziel.** *Electrical West*, volume 86, April 1941, pages 38–42.

66. Resuscitation in Gas Poisoning, Electric Shock, and Drowning (pamphlet). Published jointly by the Edison Electric Institute and the American Gas Association, 420 Lexington Avenue, New York. (Instruction in procedure to be followed in applying the Schafer Prone Pressure Method of artificial respiration.)

67. Thirteen Edison Medals Awarded Utility Employees, **M. B. Woods.** Edison Electric Institute *Bulletin*, volume 9, February 1941, pages 63–7.

68. Unique Device Developed for Standardizing Artificial Respiration Training. American Gas Association *Monthly*, volume 23, December 1941, page 434.

Bibliography on Automatic Stations, 1930*–1941

Section A

General

1930

1. Automatic Operation in Electric-Power Engineering (in German), **G. Meiners.** *AEG Mitteilungen* (Berlin), November 1930, pages 699–708.

1931

2. Automatic Control of Electrical Machinery (in Italian), **F. Fiorentini.** *L'Elettrotecnica* (Milan), volume 18, June 15, 1931, pages 394–401. Methods and apparatus for automatic control of generating plants and substations. Advantages over manual control.

3. Automatic Stations. AIEE *Transactions*, volume 50, 1931, pages 1480–7. Annual Report of the AIEE committee on automatic stations. Includes a bibliography.

1932

4. Application and Performance of Automatic Equipment at Stations and Substations of the American Gas and Electric Company System, **Philip Sporn, Basil Lanphier, Harold E. Turner.** AIEE *Transactions*, volume 51, 1932, pages 1031–46.

5. Electric Remote Supervision and Control of Power Stations (book) (in German), **M. Schleicher.** Springer (Berlin), 1932, 238 pages; bibliography, pages 230–8.

1934

6. The Technique of Remote-Control Stations (book) (in German), **W. Stablein.** R. Oldenbourg (Munich), 1934, 291 pages. Includes bibliography, pages 275–91.

1937

7. Automatic Stations. American Standard C37.2–1937. American Standards Association, New York, N. Y.

Section B (See also sections D, G, and H)

Supervisory and Remote Control—Equipments, Systems, and Methods

1930

1. Principles of Selsyn Equipments and Their Operation, **L. F. Holder.** *General Electric Review*, volume 33, September 1930, pages 500–04. Discusses principles involved, selective and multiple operation, their mechanical construction and uses.

1931

2. An A-C Supervisory Control System, **Othmar K. Marti.** AIEE *Transactions*, volume 50, 1931, pages 1352–7.

3. Measuring, Signalling, and Regulating Equipment of the Essen-Borbeck Blast Furnace Plant of F. Krupp (in German), **P. Oswald, W. Liesegang.** *Siemens Zeitschrift* (Berlin), volume 2, February 1931, pages 49–56; March 1931, pages 132–8. Illustrated description of Siemens and Halske remote control and remote measuring and indicating equipment.

4. Nature and Importance of Remote-Control Systems in the Operation of Power Plants (in German), **H. Piloty.** *Elektrotechnische Zeitschrift* (Berlin), volume 52, September 10, 1931, pages 1157–61; September 24, 1931, pages 1221–7.

5. Operating Experiences With Automatic and Supervisory Control—Automatic and Supervisory Control of Substations, **F. F. Ambuhl.** *Electrical Engineering*, volume 50, November 1931, pages 890–2.

6. Operating Experiences With Automatic and Supervisory Control—Supervisory Automatic Control of a Generating Station, **R. M. Stanley.** *Electrical Engineering*, volume 50, November 1931, pages 892–4; *Electrical World*, volume 98, July 4, 1931, pages 22–5.

7. Remote Alarms Over Telephone Circuits. *Electrical West*, volume 66, May 15, 1931, pages 354–7. An economical system of remote alarms developed by the Southern California Edison Company, Ltd., for its unattended substations is here described.

8. Remote-Control and Return-Signal Installation, Utilizing the Public Telephone Network for the Outdoor Station of the Bernische Kraftwerke A.-G. (in German) Schweizerischer Elektrotechnischer Verein Bulletin (Zurich), volume 22, no. 14, 1931, pages 333–6. Illustrated description of a remote-control system used by a Swiss power concern.

9. Remote Control Over Distribution Circuits and Without Pilot Wire (in French), **M. Chirol.** *Revue Générale de l'Electricité* (Paris), volume 30, November 14, 1931, pages 795–805. Explains a system employing a superimposed medium-frequency current for control of lighting circuits, for placing meters in circuit, and similar applications.

10. Remote Metering and Remote Control (in Swedish), **H. Fransen, E. Velander.** *Teknisk Tidsskrift* (Stockholm), May 1931, pages 77–108. A well illustrated symposium consisting of several separate articles by different Swedish engineers.

11. The Selector System of Supervisory Remote Control As Applied to the Great Indian Peninsula Railway, **W. R. Davies.** *Electrical Communications* (London), volume 9, January 1931, pages 174–83. Equipment manufacturing by Standard Telephones and Cables, Ltd.

12. Supervisory Control Equipment—Descriptive Details of Apparatus Made in England for Remote Substation Control in New Zealand. *Electrical Review* (London), volume 108, April 3, 1931, page 611.

13. Supervisory Operation Gives Control of 300 Circuits to Dispatcher; Reading Company. *Power*, volume 74, December 15, 1931, page 872.

14. A Ten Point Tandem Supervisory Control System, **N. C. Smart, W. R. Cox.** General Electric Company *Journal* (London), volume 2. November 1931, pages 146–52. System used by the General Electric Company, Ltd., England.

15. Ten Years' Experience With Automatic and Supervisory Distribution Substations, **F. F. Ambuhl.** *Electrical News and Engineering* (Toronto), volume 40, August 1, 1931, pages 35–7, 51. Experiences of the Toronto Hydro-Electric System.

16. Visicode Supervisory Control, **L. J. Cissna.** *Electric Journal*, volume 28, July 1931, pages 424–30.

This bibliography of the automatic station was prepared by the AIEE committee on automatic stations and supplements the earlier bibliographies on the subject. The material is subdivided into eight sections. In each section the entries are numbered consecutively and listed alphabetically by years, the first significant word of the title determining the alphabetical position. This bibliography was published in pamphlet form by the AIEE during 1942.

* References to 1930 and 1931 in this bibliography are supplementary to those appearing in AIEE *Transactions*, volume 50, 1931, pages 1485–7.

1932

17. An A-C Supervisory Control System, **Othmar K. Marti.** *Electrical Engineering*, volume 51, May 1932, pages 329–31.

18. Auckland Electric Power Board in New Zealand, **E. N. Tewsley.** *Metropolitan Vickers Gazette* (Manchester), volume 13, January 1932, pages 159–63. Metropolitan-Vickers supervisory control equipment.

19. Developments in Two-Wire Supervisory Systems, **J. H. Oliver.** *Electrical Engineering*, volume 51, June 1932, page 412. Abstract.

20. Electric Remote-Control and Supervision of Distribution and Transmission Networks (in French), **J. Vassilliere-Arlhac, R. Nierenberger.** Société Française des Electriciens *Bulletin* (Paris), volume 2, May 1932, pages 460–93. Supervisory-control and telemetering equipment and methods.

21. Experience With Supervisory Control, **J. E. Pastoret.** *Electrical Engineering*, volume 51, November 1932, pages 776–8. The Reading–Philadelphia suburban electrification.

22. 45,000-Kva Substation Has Supervisory Control. *Electrical World*, volume 99, January 30, 1932, page 243.

23. Group of Methods and Devices for the Control and Supervision of High-Voltage Networks Under Normal and Abnormal Operation (in French), **Doctor Schleicher, Doctor Huldschiner.** International Electrical Congress *Proceedings* (Paris), volume 6, 1932, pages 359–98.

24. Progress in Automatic and Centralized Control. *Power Plant Engineering*, volume 36, January 1, 1932, pages 44–5.

25. Protection and Centrovisory Control of the British Grid, **B. H. Leeson.** *Electrical Review* (London), volume 110, April 22, 1932, page 598.

26. Reducing Substation Costs by Extended Control, **R. DeCamp.** *Electric Journal*, volume 29, September 1932, pages 414–16.

27. Remote Alarms by Carrier-Current Over Distribution Circuit, **F. B. Doolittle.** *Electrical West*, volume 68, May 15, 1932, page 365.

28. Remote Signaling and Control on Transmission and Distribution Lines (in French), **Chirol.** International Electrical Congress *Proceedings* (Paris), volume 13, 1932, pages 357–71.

29. Remote Signalling and Recording of Switching Operations (in German), **W. Gellinek, H. Kunow.** *Siemens Zeitschrift* (Berlin), volume 12, October 1932, pages 370–7.

30. Split-Second Supervisory Control (principle of Polaricode), **M. E. Reagan.** *Electric Journal*, volume 29, June 1932, pages 298–301, 303.

31. Supervisory Control. *Electrician* (London), volume 109, August 5, 1932, page 177. Remote control by selective systems and elimination of confused orders.

32. Supervisory Control for A-C Electrified Railroads, **C. P. West, H. C. Griffith.** AIEE *Transactions*, volume 50, 1931, pages 1358–62. For remote operation of high-voltage a-c step-down substations of the Pennsylvania Railroad.

33. Supervisory Control for Reading Electrification, **G. I. Wright.** *Electrical World*, volume 99, March 5, 1932, pages 454–7.

34. Supervisory Control for 220-Kv Station. *Electrical West*, volume 69, December 1932, pages 228–30. As applied to govern the equipment necessary for a 220-kv tie.

35. System Operator Sees the System, **S. M. Hamill, Jr.** *Electrical World*, volume 100, September 24, 1932, pages 406–08. Features developed in telephone practice find use in power system control.

36. Telemetering, Supervisory Control, and Associated Communication Circuits. *Electrical Engineering*, volume 51, September 1932, pages 613–20. Essentially the full text of an AIEE joint subcommittee report.

37. World's Largest Supervisory System for New York Subway, **F. E. Jaquay, L. D. White.** *Electrical World*, volume 100, August 13, 1932, pages 204–06.

1933

38. Automatic Remote-Control Apparatus (in German), **Manfred Schleicher.** *Siemens Zeitschrift* (Berlin), volume 13, May, June 1933, pages 88–94.

39. Communication, Protection, and Supervisory-Control Systems for Electric-Power Networks. General Electric Company *Journal* (London), volume 4, August 1933, pages 165–74.

40. Contactor Signals When Breaker Opens, **H. B. Taverner.** *Electrical World*, volume 102, December 16, 1933, page 789.

41. Direct Selection System of Supervisory Control, **M. E. Reagan.** AIEE *Transactions* volume 52, 1933, pages 240–4. Principles of the direct selection system of supervisory control.

42. A Grid Supervisory Scheme. *Electrical Review* (London), volume 113, July 14, 1933, page 46.

43. Guarding Remote Control Against Ground Faults, **G. H. Landis, H. A. McLauglin.** *Electrical World*, volume 101, January 14, 1933, pages 76–8.

44. Improved Power Supply Betters Street Railway Service, **J. A. Noertker.** *Electrical Engineering*, volume 52, January 1933, pages 22–8. Includes an account of the automatic substation equipment of the Cincinnati Street Railway Company.

45. Observations on Ten Years' Operation of Supervisory Control, **Leslie R. Hicks.** *Electrical World*, volume 102, December 30, 1933, pages 859–60.

46. Panama Canal Uses Supervisory Power-System Control, *Power*, volume 77, November 1933, page 571.

47. Remote Control and Indication. *Electrical Review* (London), volume 112, April 21, 1933, page 560.

48. Remote Control by the Single-Wire Method (in German), **W. Venzke.** *AEG Mitteilungen* (Berlin), July 1933, pages 155–8.

49. Superposition of the "Telenerg System" on Large High-Voltage Networks (in German), **W. Zur Megede.** *Siemens Zeitschrift* (Berlin), volume 13, July, August 1933, pages 165–9. The use of audio-frequency currents of 280 to 600 cycles on 50-cycle power networks for the remote control of multiple-rate meters on the consumer's premises.

50. Supervisory Control at the Panama Canal, **C. C. Lehman.** *Electric Journal*, volume 30, September 1933, pages 371–5.

51. Supervisory Control for Pumping Stations, **R. C. Allen.** *Electric Journal*, volume 30, May 1933, pages 183–6. Illustrated description of the Westinghouse Electric Pumping and control equipment in a new waterworks plant at Erie, Pa.

52. Supervisory Control Gear (abstracts and discussions), **E. M. S. McWhirter.** *Electrician* (London), volume 110, March 24, 1933, page 382; *Electrical Review* (London), volume 112, March 24, 1933, pages 417–18. Supervisory distant control.

53. Supervisory System Controls Pump House. *Electrical West*, volume 70, March 1, 1933, pages 94–6. "Modern control electrically heated pump house, thermostatic alarms, buried cable system, and 3,153-foot lift are unusual features of Grand Canyon pumping plant of 'The Santa Fe'."

1934

54. Apparatus for Remote Supervision of the Operation of Circuit Breakers (in French), **François H. Wallenborn.** *Revue*

Générale de l'Electricité (Paris), volume 35, June 2, 1934, pages 757–60. Siemens-Schuckert supervisory-control apparatus.

55. Application of Automatic Voltage and Switch Control to Electrical Distribution Systems, **W. Kidd, J. L. Carr.** Institution of Electrical Engineers *Journal* (London), volume 74, April 1934, pages 285–322; discussion, volume 74, June 1934, pages 535–42. *Electrical Review* (London), volume 113, December 8, 1933, pages 805–06; abstract, December 15, 1933, page 842. *Electrician* (London), volume 111, December 8, 1933, pages 718–19; discussion, December 15, 1933, page 748. Voltage regulation and supervisory control.

56. Bankside Control Room of the Central Electricity Board. *Electrician* (London), volume 112, January 26, 1934, pages 95–8; *Engineer* (London), volume 157, April 27, 1934, pages 426–7; *Engineering* (London), volume 137, April 27, 1934, pages 497–8.

57. Carrier Control Isolates Trouble on Tap Lines, *Electrical World*, volume 103, March 31, 1934, page 469. General Electric carrier-current equipment used for control of tap lines.

58. Communication, Protection, and Supervisory-Control Systems for Electric Power Networks. General Electric Company *Journal* (London), volume 5, May 1934, pages 115–22.

59. The Communication and Supervisory Control System of the Grampian Electricity Supply Company, **F. B. Willis.** General Electric Company *Journal* (London), volume 5, November 1934, pages 234–44.

60. Modern Practise in Germany and the European Continent With Regard to Supervisory Control Systems As Applied to Large Interconnected Supply Areas, **M. Schleicher.** Institution of Electrical Engineers *Journal* (London), volume 75, December 1934, pages 710–29.

61. Outdoor Metal-Clad Switchgear and Centrovisory Control Equipment. *Engineer* (London), volume 158, August 17, 1934, pages 170–2.

62. And Now, Polaricode Junior, **M. E. Reagan.** *Electric Journal*, volume 31, March 1934, pages 110–12. Latest member of the supervisory control family.

63. A Simple Arrangement for Tripping the Breakers on Consumers' Power Circuits at Time of Peak Load (in French), **J. de Puymorin, G. Remenieras.** *Revue Générale de l'Electricité* (Paris), volume 35, February 1934, pages 157–60. An automatic arrangement for disconnecting certain consumers at certain times.

64. Some New Developments in Supervisory Control, **M. E. Reagan.** AIEE *Transactions*, volume 53, 1934, June section, pages 949–52.

1935

65. Automatic Equipment for the Supervisory Control of Power and Converter Stations (in Swedish), **Hans Eger.** *ASEA'S Tidning* (Västeras), volume 27, August 1935, pages 118–25. Illustrated description of Allmanna Svenska Elektriska Aktiebolaget equipment.

66. Automatic Supervisory System. *General Electric Review*, volume 38, May 1935, page 252.

67. Carrier-Current Switching for the Canandaigua 33,000-Volt Line, **H. J. Klumb.** *Rochester Gas and Electric News*, volume 19, February 1935, pages 402–07. Illustrated description of an installation on the lines of the Rochester Gas and Electric Company.

68. Central Supervisory Control for Electric Power Plants in Stockholm (in Swedish), **H. Ahlen.** *ASEA'S Tidning* (Västeras), volume 27, February 1935, pages 18–23; (in English) *ASEA Journal* (Västeras), volume 12, January–March 1935, pages 2–7.

69. Outages Signaled in Employee's Home, **Kenneth N. Reardon.** *Electrical World*, volume 105, September 28, 1935, page 2360.

70. Principles of Remote Supervision of Electric Systems (in French), **W. Howald.** *Schweizerischer Elektrotechnischer Verein Bulletin* (Zurich), volume 26, number 17, 1935, pages 477–84.

71. Remote-Control Equipment on the Wannsee Railroad (in German), **W. Draeger.** *Siemens Zeitschrift* (Berlin), volume 15, July 1935, pages 319–23. Illustrated description of Siemens-Schuckert remote control for a suburban railway line near Berlin.

72. Remote Control on Distribution Networks Without the Use of a Pilot Wire (in French), **Michel Durepaire.** Société Française des Electriciens *Bulletin* (Paris), volume 5, May 1935, pages 513–25.

73. Remote Indication, Supervisory System Installed on Winchester Corporation's Electricity Supply Network. *Electrician* (London), volume 114, April 5, 1935, pages 447–8; *Engineer* (London), volume 159, May 17, 1935, page 522; *Electrical Review* (London), volume 117, August 23, 1935, page 243.

74. Remote Supervisory Control of Switchgear, **S. E. Newman, R. T. Lythall.** *English Electric Journal* (London), volume 7, January 1935, pages 103–09.

75. Sectional Layout for Supervisory Control and Telemechanics (in Russian), **D. V. Svetcharnik.** *Elektrichestvo* (Moscow), November 1935, pages 10–17.

76. Supervisory Control Improves Service on the Indianapolis System, **H. Roempke, L. J. Cissna.** *Electric Journal*, volume 32, April 1935, pages 147–50.

77. Supervisory Control of Substations, Equipment Used on the Marseille Network (in French), **Sauvaire.** *L'Industrie des Voies Ferrées et des Transports Automobiles* (Paris), volume 29, February 1935, pages 48–53; July 1935, pages 180–6.

78. What Is Speed in a Supervisory System? **A. E. Anderson.** *General Electric Review*, volume 38, March 1935, pages 132–4.

1936

79. "Automatics" (in Russian), **A. Solodovnikov.** *Avtomatika i Telemekhanika* (Moscow), number 2, 1936, pages 109–26. Studies the fundamentals of automatic and remote control of mechanisms.

80. Boulder Canyon Project; Carrier Current, **C. P. Garman.** *Electric Journal*, volume 33, November 1936, pages 501–03.

81. The Brown Boveri Remote-Control System, **O. Plechl.** *Brown Boveri Review* (Baden), volume 23, July 1936, pages 179–85. Includes consideration of both remote-control and telemetering equipment.

82. Control and Communication System of the Schwarzenbach Water-Works (in German), **W. Knapp.** *Siemens Zeitschrift* (Berlin), volume 16, April 1936, pages 119–22.

83. Development of Supervisory-Control System. *Nippon Electrical Communication Engineering* (Tokyo), September 1936, pages 275–302. Japanese methods and equipment of the Nippon Electric Company, Ltd.

84. Electrical Equipment for Waterworks Systems, **S. A. Canariis.** AIEE *Transactions*, volume 55, 1936, January section, pages 36–40. Application of supervisory control equipment and electric pump drive to municipal waterworks.

85. "Fassung 3" Remote-Controlled Pumping Plant of the Stuttgart Municipal Water Supply (in German), **H. Haas.** *Brown Boveri Nachrichten* (Baden), volume 23, October–December 1936, pages 136–40. An installation of Brown Boveri Company equipment.

86. Faults in Electric Systems and Their Correction by Means of Remote Indication and Remote Control (in French), **P. de Bremaecker.** Société Belge des Electriciens *Bulletin* (Brussels) volume 52, January 1936, pages 17–30; February 1936, pages 69–88; March 1936, pages 141–54.

87. From Remote Indication to Remote Control (in French), **M. Granat.** Société Belge des Electriciens *Bulletin* (Brussels), volume 52, January 1936, pages 1–16; February 1936, pages 101–15.

88. Mechanical Resonance Relays for Remote Control Without Pilot Wires (in French), **Marius Lavet.** Société Française des Electriciens *Bulletin* (Paris), volume 6, January 1936, pages 81–104.

89. New Remote-Control Devices (in German), **O. Plechl.** *Brown Boveri Review* (Baden), volume 23, October–December 1936, pages 141–49. Illustrated description of Brown Boveri Company equipment.

90. Pennsylvania Installs Supervisory Controls, **E. H. Brown, C. Romanovsky.** *Electrical World*, volume 106, January 18, 1936, pages 215–17.

91. Problems of Telemechanics and Automatic Control in Electric Networks (in Russian), **V. V. Nedelko.** *Elektrichestvo* (Moscow), volume 17, September 1936, pages 17–21.

92. Remote-Control Installation for the Power-Supply System of the City of Milan (in German), **L. Volker.** *Elektrotechnische Zeitschrift* (Berlin), volume 57, January 9, 1936, pages 33–6.

93. Remote Control of Power Networks, **G. A. Burns, T. R. Rayner.** Institution of Electrical Engineers *Journal* (London), volume 79, July 1936, pages 95–125; discussion, volume 79, September 1936, pages 381–5. *Electrician* (London), volume 116, February 14, 1936, page 204.

94. Remote Control, Without Pilot Wire, on the Three-Wire Direct-Current Zone of the Compagnie Parisienne de Distribution D'Electricité (in French), **Michel Durepaire, Andre Perlat.** *Revue Générale de l'Electricité* (Paris), volume 40, August 1, 1936, pages 149–59. Illustrated description of equipment and methods used in a scheme for the remote control of lights, signals, multi-rate meters, and so forth. Low frequency is superimposed on direct current.

95. Remote Indication of the Operation of Automatic Reclosing Circuit Breakers, **J. G. Park.** *Electrical Times* (London), volume 90, July 30, 1936, page 151.

96. Remote Supervision and Control of Circuit Breakers in Stations With Operating Personnel (in German), **O. Plechl.** *Elektrotechnik und Maschinenbau* (Vienna), volume 54, August 30, 1936, pages 421–6.

97. Remote Supervisory Control Installation at Ipswich. *Electrician* (London), volume 117, July 17, 1936, pages 81–2; *Electrical Review* (London), volume 119, July 31, 1936, page 149; *Engineer* (London), volume 162, July 31, 1936, pages 117–18.

98. Supervisory Control and Remote Metering, **J. V. B. Duer.** Installations on the electrified section of the Pennsylvania Railroad. AIEE *Transactions*, volume 55, 1936, January section, pages 70–75; 1936, August section, page 890.

99. System for the Remote Indication of Oil Circuit Breaker Positions in the System of the Styrian Wasserkraft und Elektrizitats A.G. (in German), **Hans Eigl.** *Elektrotechnik und Maschinenbau* (Vienna), volume 54, October 25, 1936, pages 509–13.

100. What Type Supervisory System Shall Be Chosen? **W. P. Simpson.** *Electrical World*, volume 106, March 14, 1936, pages 750–1, 814.

1937

101. Allgemeine Elektrizitats Gesellschaft Remote-Control System Used on the Wannsee Railway (in German), **W. Draeger.** *Elektrische Bahnen* (Berlin), volume 13, February 1937, pages 44–7.

102. The Asea Supervisory System As Applied to the Southern Railway, England, **Carl Kiessling, Holger Ahlen.** *ASEA Journal* (Västeras), volume 14, December 1937, pages 174–87. Illustrated description of equipment for the control of unattended semi-automatic substations, remote indication, remote metering, and so forth.

103. Carrier-Current Supervisory Control and Relaying; (Boulder Dam Power System) Progress in Engineering in 1936, **H. W. Cope.** *Electric Journal*, volume 34, January 1937, page 9.

104. Control Rooms and Control Equipment of the Grid System, **J. D. Peattie.** Institution of Electrical Engineers *Journal* (London), volume 81, November 1937, pages 607–18; discussion: volume 81, November 1937, pages 618–24; December 1937, pages 790–1. *Engineer* (London), volume 163, February 12, 1937, page 184. *Electrical Review* (London), volume 120, February 12, 1937, pages 258–9.

105. The Effect of Selective Protection and Remote Operation, on the Development of Networks (in German). **Manfred Schleicher.** *Electrotechnische Zeitschrift* (Berlin), volume 58, March 4, 1937, pages 235–7.

106. High-Frequency Telephony and Remote Control on the 220-Kv Network of the Krangede Aktiebolaget (in German), **Gustaf Lofgren.** *AEG Mitteilungen* (Berlin), July 1937, pages 227–32.

107. Relay Selector System for Remote Supervision of Substations (in German). *AEG Mitteilungen* (Berlin), December 1937, pages 450–3.

108. Remote Control by the Selector System, **W. Venzke.** *AEG Progress* (Berlin), November 2, 1937, pages 30–2.

109. Remote Control of a Network (in German), **G. Meiners.** *Zeitschrift fuer Fernmeldetechnik* (Munich and Berlin), volume 18, July 1937, pages 105–08.

110. Simplified Circuit-Breaker Supervisory System With Selector Relay (in German), **W. Henning.** *Siemens Zeitschrift* (Berlin), volume 17, October 1937, pages 521–5.

111. Some Basic Points on Distant Control System for Moscow Underground Railway Substations (in Russian), **L. G. Rashkovski.** *Elektrichestvo* (Moscow), number 6, March 1937, pages 22–30.

1938

112. AEG Selector-Type Remote-Control Equipment (in German), **W. Venzke.** *AEG Mitteilungen* (Berlin), September 1, 1938, pages 459–63; October, 1938, pages 491–6. A serial article of which the first installment covers general features and mode of operation, and the second, operation and design.

113. Centralized Control of Loads. *Electrical Review* (London), volume 123, October 7, 1938, page 155. A system of remote control in which frequencies between 300 and 800 cycles are superimposed on the a-c or d-c supply circuit. Developed by the General Electric Company, Ltd., England.

114. Centralized Control of Railway Substations (in French), **M. M. Garreau.** Société Française des Electriciens *Bulletin* (Paris), volume 8, November 1938, pages 1007–22. Methods used on the electrified line from Paris to Le Mans.

115. Centralized Control for the Traction Substations of the Paris-Mans Electrified Section of the French Government Railways (in French), **M. M. Garreau.** *Revue Générale de l'Electricité* (Paris), volume 43, June 4, 1938, pages 719–30.

116. Factors Influencing the Selection of Remote-Control System and Transmission Channel (in German), **W. Venzke.** *Elektrotechnische Zeitschrift* (Berlin), volume 59, November 24, 1938, pages 1253–7; December 1, 1938, pages 1292–4.

117. A New System of Remote Control, **Charles N. Kimball.** *RCA Review*, volume 2, January 1938, pages 303–16. A carrier-current system.

118. Network Operation Simplified by Supervisory System, **Earle Wild.** *Electrical World*, volume 109, May 21, 1938, pages 1674–6. "Recorders and visual indicators in (Chicago) load dispatcher's office show protector positions and operations and conditions of transformers in network vaults."

119. Possibilities of Remote Control by Means of Siemens Remote-Control Systems Involving the Selector Method (in German), **W. Henning.** *Siemens Zeitschrift* (Berlin), volume 18, August 1938, pages 402–06; September 1938, pages 440–6.

120. Protection and Remote Control; How and When to Modernize a Protective System (in Italian), **E. Maggi.** *L'Elettrotecnica* (Milan), volume 25, November 25, 1938, pages 810–14.

121. Reaction of "Transcommando" Signaling on Three Phase Supply Systems (in German), **V. Aigner, K. Hessenberg.** *Archiv fuer Elektrotechnik* (Berlin), volume 33, number 7, 1939, pages 419–39.

122. Remote Control of Network Protectors, **W. R. Brownlee, W. E. Dent, Jr.** AIEE *Transactions*, volume 57, 1938, December section, pages 685–92. Includes a list of nine references.

123. Remote Control Systems (in Swedish), **N. O. Berlin.** *Teknisk Tidskrift* (Stockholm), volume 68, March 5, 1938, pages 41–6.

124. A Self-Checking System of Supervisory Control, **M. E. Reagan.** AIEE *Transactions*, volume 57, 1938, October section, pages 600–05. A new type of supervisory-control system which was developed to reduce the selection time in large multistation applications.

125. Siemens Selective Remote-Control System (in German), **W. Henning.** *Siemens Zeitschrift* (Berlin), volume 18, May 1938, pages 255–60.

126. Simplified Remote-Control System for Network Operation (in German), **S. John, J. Sorge.** *Siemens Zeitschrift* (Berlin), volume 18, July 1938, pages 351–5. Describes the improvements made in the single-conductor control.

127. "Transkommando" Telecontrol System (in German). *AEG Mitteilungen* (Berlin), March 1938, pages 116–20. Illustrated description of an AEG telecontrol system in which impulses are impressed on a high tension conductor by interrupting the current momentarily.

1939

128. Audio-Frequency Channels for Remote-Control Purposes (in German), **G. Kleinschnitz, G. Kummert.** *AEG Mitteilungen* (Berlin), April 29, 1939, pages 229–32. "In the audio-frequency method of telemetering or remote control, the sending relay switches on a source of audio-frequency current instead of the customary d-c impulse, and the a-c is rectified at the receiver and operates the gear in the usual manner."

129. Centrovisory and Automatic Load Control Equipment. *Electric Railway Traction supplement to Railway Gazette and Railway News* (London), March 3, 1939, pages 24–6. "A description of the system in use on the 1,500-volt d-c lines of the New Zealand Government Railways."

130. Layout of Remote-Control Installations (in Italian), **E. Immirzi.** *L'Elettrotecnica* (Milan), volume 26, January 10, 1939, pages 6–10.

131. Multiple Working of Remote-Control Circuits (in German), **K. H. Podszeck.** *Siemens Zeitschrift* (Berlin), volume 19, November 1939, pages 519–26. Various types of apparatus used for telemetering and remote control of electric power systems are described in detail with circuit diagrams.

132. Remote-Control Equipment Employing Selective Relays (in German), **W. Henning.** *Siemens Zeitschrift* (Berlin), volume 19, January 1939, pages 38–42.

133. Remote Control of the Rectifier and Converter Substations of the Hanover-Brunswick Current Supply Company, Hanover (in German), **A. Schutte, J. Klinker.** *Siemens Zeitschrift* (Berlin), volume 19, June 1939, pages 259–63. The authors describe the remote control system installed in 1936 in one of the rectifier substations serving for traction supply and rural distribution.

134. Remote Control System on Electrical Distribution Networks (in Italian), **C. Calosi.** *L'Elettrotecnica* (Milan), volume 26, November 25, 1939, pages 694–700.

135. Remotely-Controlled and Automatic-Rectifier Plant (in German), **E. Schroder.** *Siemens Zeitschrift* (Berlin), volume 19, February 1939, pages 78–87. Describes methods, connections, and equipment used.

136. Remote Supervisory Control. *Engineer* (London), volume 168, November 10, 1939, pages 464–5, 467; November 17, 1939, pages 489–92; November 24, 1939, pages 512–15; December 1, 1939, pages 540–1; December 8, 1939, pages 561–4; December 15, 1939, pages 586–8; December 22, 1939, pages 610–13.

137. Symposium on Operation of the Boulder Dam Transmission Line—Carrier-Current Equipment. **J. D. Laughlin.** AIEE *Transactions*, volume 58, 1939, April section, pages 147–51.

1940

138. Automatic Supervisory Control for a Pumping Scheme. *Engineer* (London), volume 169, April 19, 1940, page 385.

139. Carrier Control Is Faster Than "Hunt Fault" Procedure, **Harold W. Coffin.** *Electrical World*, volume 113, January 27, 1940, pages 290–1, 340–1.

140. Carrier-Current Losses Measured and Interference Minimized on Boulder–Los Angeles Transmission Lines, **J. D. Laughlin, W. E. Pakala, M. E. Reagan.** AIEE *Transactions*, volume 59, 1940, January section, pages 4–10.

141. Remote Supervisory Control on the Wirral Railway; Strowger Remote Phototelemetering Equipment. *Engineer* (London), volume 169, February 9, 1940, pages 126–7.

142. "Rhythmatic" Control, **J. F. Mackenzie.** *Strowger Journal*, volume 5, August 1940, pages 42–61. System of remote switching by means of control currents superimposed on ordinary power-distribution mains.

143. "Ripplay," **R. M. A. Smith.** *Metropolitan Vickers Gazette* (Manchester), volume 19, October 1940, pages 76–80. Design of a remote-control apparatus including details of the receiving unit and a description of the central-station equipment.

144. Simple Control Sectionalizes Important Industrial Loop, **H. A. P. Langstaff, K. N. Reardon.** *Electrical World*, volume 113, April 6, 1940, pages 1065–7. Telephone lines leased for air-break switch operation.

1941

145. Cable Supervisory Control Simplified, **C. E. Stewart.** *Electrical World*, volume 115, May 31, 1941, page 1861.

146. Centralized Remote Control. *Electronics and Television* (London), volume 14, April 1941, pages 165–7. Details of a "ripple-control" system developed by the General Electric Company, Ltd., England. An audio-frequency current is injected into the regular supply circuit to operate relays for signaling or control purposes.

147. Remote and Supervisory Control (in German), **W. Henning.** *Zeitschrift des Vereines Deutscher Ingenieure* (Berlin), volume 85, May 10, 1941, pages 431–9. A review of progress; gives a reference list of 23 items.

148. Telemetering, Supervisory Control, and Associated Circuits, AIEE committee report. AIEE *Transactions*, volume 60, 1941, pages 1411–34.

Section C (See also section B)

Telemeters and Telemetry—Types of Instruments, Systems and Methods

1930

1. AEG Compensation Telemetering System and Its Applications (in German), **W. Schafer.** *AEG Mitteilungen* (Berlin), June 1930, pages 412–15.

1931

2. Account of Modern Practice and Tendencies With Particular Reference to Summation Meters and to Their Importance in Connection With Electricity-Supply Systems. **W. Janicki.** International Conference on Large High-Voltage Electric Systems (CIGRE, Paris), volume 1, 1931, pages 753–87.

3. Application for Remote-Measuring Devices (in German), **Walter Stern.** *Elektrotechnische Zeitschrift* (Berlin), volume 52, February 26, 1931, pages 268–9. Brief description of a device for the remote measurement of active and reactive power.

4. Characteristics and Possible Applications of the More Important Remote-Measuring Systems (in German), **Schafer.** *AEG Zeitung* (Berlin), October 1931, pages 177–83.

5. Choice of System in Remote Metering (in German), **W. Bruckel.** Verein Deutscher Electrotechniker *Fachberichte* (Berlin), 1931, pages 111–14.

6. Device for the Remote Indication of Levels or Positions (in French), **J. Laisne.** *Revue Générale de l'Electricité* (Paris), volume 29, April 25, 1931, pages 665–7.

7. Differential Circuits Involving Resistance-Type Transmitters and Inductive Meters That Are Independent of Voltage, for the Electrical Integration of Thermal Quantities (in German), **Wilhelm Geyger.** *Archiv fuer Elektrotechnik* (Berlin), volume 25, number 11, 1931, pages 769–75.

8. Electric Telemetering (in Russian), **V. I. Brandenburger.** *Elektrichestvo* (Moscow), number 17, September 1931, pages 965–71. German practice.

9. Electric Transmission of Water-Level Readings (in German). *Deutsche Wasserwirtschaft* (Munich), volume 26, October 1, 1931, pages 185–8. Illustrated description of apparatus and method.

10. On the Measurement of Very Low Frequencies and Its Application to Remote Measurements (in German), **E. Hudec.** *Elektrotechnische Zeitschrift* (Berlin), volume 52, March 19, 1931, pages 380–5.

11. Remote Electric Indication of Meter Readings, Especially Remote Totalizing and Its Importance in Electric-Distribution Systems (in French), **V. Janicki.** Société Française des Electriciens *Bulletin* (Paris), volume 1, April 1931, pages 341–86.

12. Remote Indicating Equipment (in Italian), **G. Sartori.** *L'Elettrotecnica* (Milan), volume 18, May 5, 1931, pages 303–07.

13. Remote Measurements of Electrical Quantities in Power-Plant Operation (in German), **Fredy Ruegg.** Schweizerischer Elektrotechnischer Verein *Bulletin* (Zurich), volume 22, number 6, 1931, pages 137–46.

14. Remote Metering and Remote Control (in Swedish), **H. Fransen, E. Velander.** *Teknisk Tidskrift* (Stockholm), May 1931, pages 77–108. A well illustrated symposium consisting of several separate articles by different Swedish engineers.

15. Remote Transmission of Measurements by Means of the Induction-Type Dynamometer (in Italian), **G. Induni.** *L'Elettrotecnica* (Milan), volume 18, October 25, 1931, pages 760–3.

16. Solution of the Problem of Distant Measuring and Totalization, **B. Usigli.** International Conference on Large High-Voltage Electric Systems (CIGRE, Paris), volume 1, 1931, pages 365–8.

17. System of Remote Measuring by Means of the Induction Electrodynamometer, **F. J. C. Vettiner.** International Conference on Large High-Voltage Electric Systems (CIGRE, Paris), volume 2, 1931, pages 161–72.

18. "Telect" System of Telemetering (in French), **Vassilliere.** Société Française des Electriciens *Bulletin* (Paris), volume 1, June 1931, pages 629–32.

19. Telemeter Measurements for Electric Transmission Lines and Light-Impulse System (in Russian), **M. L. Zukkerman.** *Elektritchestvo* (Moscow), number 21, part 1, November 1931, pages 1207–15.

20. Telemetering (in Italian), **L. Selmo.** *L'Elettrotecnica* (Milan), volume 18, July 5, 1931, pages 446–51. Classifies the various systems into three main divisions, giving the principles and applications of each.

21. A Vacuum-Tube Device for Current-Balance Telemeters, **B. E. Lenehan, Paul MacGahan.** *Electrical Engineering*, volume 50, July 1931, pages 510–11.

1932

22. Automatic Indication of Water Levels (in French), **Despujols.** International Electrical Congress *Proceedings* (Paris), volume 13, 1932, pages 345–56.

23. "Chronoflow" Electrically Operated Remote-Reading Fluid Meters. *Instruments*, volume 5, October 1932, page 244.

24. Electric Integration of Thermal Quantities by Means of Resistance-Type Remote Transmitters and Induction Meters That Are Independent of the Voltage (in German), **Wilhelm Geyger.** *Archiv fuer Elektrotechnik* (Berlin), volume 26, number 2, 1932, pages 94–8.

25. Electric Power Supply—Protective, Measuring and Controlling Apparatus (in German), **F. Niethammer.** Verein Deutscher Ingenieure *Zeitschrift* (Berlin), volume 76, July 23, 1932, pages 717–23.

26. Electrical Telemetering, **H. Olken.** *Instruments*, volume 5, March 1932, pages 66–74, 91–2. Includes a list of seven bibliographic references.

27. Interchangeable Unit System for Telemetering Installations (in German), **M. Schleicher.** *Siemens Zeitschrift* (Berlin), volume 12, September 1932, pages 299–303. (In English) *Siemens Review* (Berlin), volume 9, number 1, 1933, pages 6–10. The "Box-of-Brick" System in remote-measurement plants.

28. Methods for Summation Measurements With Electric Telemetering Equipment, and Their Fundamental Errors (in German), **W. Stablein.** *Elektrotechnik und Maschinenbau* (Vienna), volume 50, January 31, 1932, pages 69–76.

29. Photo-Electric Telemeters Used on Southern System, **A. J. Johnston, T. A. Busby.** *Electrical World*, volume 99, February 27, 1932, page 414.

30. Remote Reading of Watt-Hour Meters, **A. S. Fitzgerald.** *Electrical Engineering*, volume 50, December 1931, pages 942–4; *Power Plant Engineering*, volume 36, March 1, 1932, pages 219–20.

31. Remote Reading of Watt-Hour Meters, **W. A. Leidigh.** Northwest Electric Light and Power Association engineering section, meter committee report; April 13–15, 1932, pages 16–17.

32. Telemeter Uses Tubes and Standard Instrument Parts,

A. J. Johnston. *Electrical World*, volume 99, June 25, 1932, pages 1089–91.

33. Telemetering by Means of the Iron-Ring Type of "Quotient Meter" (in German), **Wilhelm Geyger.** *Archiv fuer Elektrotechnik* (Berlin), volume 26, number 7, 1932, pages 535–8. The author's "quotient meter" is an instrument developed to minimize temperature effects in the lines used for measuring certain quantities at a considerable distance.

34. Telemetering by the Impulse-Compensation Method (in German), **H. Dallman.** *AEG Mitteilungen* (Berlin), March 1932, pages 80–3.

35. The Torque-Balance Telemeter, **A. J. Johnston.** AIEE *Transactions*, volume 51, 1932, pages 1027–30.

36. The Use of Telephone Facilities for Telemetering, **J. L. Clarke.** *Electrical News and Engineering* (Toronto), volume 41, May 15, 1932, pages 33–7.

1933

37. Central Instrument for Temperature Measurement, Indication, and Signalling (in Swedish), **H. Wennlund.** *ASEA Tidning* (Västeras), volume 25, July 1933, pages 102–07.

38. Industrial Electrical Measuring Instruments (book), **K. W. E. Edgcumbe, Kenelm, F. E. J. Ockenden.** 3d Edition, 1933, 553 pages, Isaac Pitman and Sons, New York, N. Y. Telemeters and Telemetry, pages 438–57.

39. Measuring Angular Velocities by Means of Indicating and Recording Instruments of the Ohmmeter Type (in German), **W. Geyger.** *Archiv fuer Elektrotechnik* (Berlin), volume 27, number 7, 1933, pages 505–10. A method of telemetry for electrical, mechanical, and thermal quantities.

40. New Compensation Method for the Electric Remote Transmission of Indicated Readings (in German), **Wilhelm Geyger.** *Elektrotechnische Zeitschrift* (Berlin), volume 54, December 7, 1933, pages 1187–90.

41. Rate and Quantity Records Transmitted Over Telephone Circuits, **Charles G. Richardson.** *Power*, volume 77, June 1933, pages 304–05. Describes the system of telemetering mechanical quantities known as the "chronoflo."

42. Some Electrical Methods of Remote Indication, **C. Midworth, G. F. Tagg.** Institution of Electrical Engineers *Journal* (London), volume 73, July 1933, pages 33–48. Deals primarily with the principles on which some electrical methods of remote indications are based.

43. Telemetering and Remote Control (in French), **J. Vassilliere-Arlhac.** Société Française des Electriciens *Bulletin* (Paris), volume 3, January 1933, pages 45–70. Discusses a-c, d-c, and impulse systems.

44. Telemetering System and Example of Installation (in Japanese), **Z. Shiota.** OHM (Tokyo), volume 20, November 1933, pages 625–7.

45. Telemetering With Supervisory Control, **G. DeCroce.** *Electric Journal*, volume 30, June 1933, pages 260–3.

46. The Torque-Balance Telemeter, **C. D. Osterland.** *Electrical Canada* (Toronto), April 1933, pages 7–10, 23.

1934

47. Application of Epicycloidal Gears to Problems of Kinematic Mechanics; Remote Measurements or Control by Means of Differential Gearing (in French), **F. E. Myard.** *Génie Civil* (Paris), volume 104, June 16, 1934, pages 533–6.

48. Electric Power Metering (book), **Archer E. Knowlton.** McGraw-Hill Book Company, Inc., New York, N. Y., 1934, 340 pages. Telemetry, page 300–24.

49. Electric Remote Indicator of Water-Level (in German), **G. Salis.** *Schweizerische Bauzeitung* (Zurich), volume 103, March 31, 1934, pages 150–2.

50. Electric Remote Transmission of Indicator Readings by Means of Nonreactive A-C Transmitting Devices (in German), **Wilhelm Geyger.** *Archiv fuer Electrotechnik* (Berlin), volume 28, number 11, 1934, pages 689–94.

51. Electronic Relay-Operated Potentiometer Pyrometer. *Instruments*, volume 7, April 1934, pages 76–7.

52. An Improved High-Rate Impulse Telemeter System, **Carl Oman.** *Electric Journal*, volume 31, August 1934, pages 313–15.

53. Indicating, Recording, and Integrating Fluid Meters. *Instruments*, volume 7, April 1934, page 80.

54. Induction-Type Transmitter for Rate of Flow and Liquid Level Indications (in German), **H. Lohmann, F. von Grundherr.** *Siemens Zeitschrift* (Berlin), volume 14, February 1934, pages 47–53.

55. Interconnection Economies Through Telemeter Totalizing, **W. J. Lank.** *Electrical World*, volume 103, June 30, 1934, pages 948–9.

56. Investigation of the Time Factor in Its Relation to the Measured Value and the Indicated Value in Telemetering, Especially in Connection With Continuous Transmission (in German), **H. Dallmann.** *Archiv fuer Electrotechnik* (Berlin), volume 28, number 7, 1934, pages 432–45. A study of the errors introduced by inertia of the transmitting apparatus.

57. Load Totalizing in the New York Area, **F. Zogbaum.** AIEE *Transactions*, volume 53, 1934, June section, pages 886–9; discussion, 1934, November section, pages 1529–30. "A remote-metering system operating over telephone lines to bring load indications directly to the office of the system operator from important stations in the metropolitan area."

58. New Electric Transmitting and Metering Device for Thermodynamic Measuring Instruments (in German), **H. Dallmann.** *AEG Mitteilungen* (Berlin), May 1934, pages 155–8. Telemetering equipment that is independent of the voltage and which can be connected directly to the network.

59. A New Telemetering System (Bailey). *Power Plant Engineering*, volume 38, December 1934, page 611; *Steel*, volume 95, October 15, 1934, page 61.

60. Operating Speed of Remote Indication and Control Systems (in German), **R. Koberich.** Verein Deutscher Electrotechniker *Fachberichte* (Berlin), 1934, pages 35–7.

61. Remote-Measuring Devices for the Operation of Electric Systems (in German), **A. Linker.** *Elektrotechnische Zeitschrift* (Berlin), volume 55, August 30, 1934, pages 857–60. Includes 27 bibliographic footnotes.

62. Selsyn Instruments for Position Systems, **T. M. Linville, J. S. Woodward.** AIEE *Transactions*, volume 53, 1934, June section, pages 953–60.

63. Tallymeters and Tallygraphs. *World Power* (London), volume 22, August 1934, pages 77–8. British telemetering equipment.

64. A Telemeter With Pilot-Coil Transmitter, **L. J. Lunas, H. L. Bernarde.** AIEE *Transactions*, volume 53, 1934, June section, pages 974–6; discussion, December 1934, pages 1660–1. "The feature of the current-type telemeter in this paper is the pilot coil which acts as a detector of load changes."

1935

65. Telemetering Equipment (in German), **A. Trenner.** *AEG Mitteilungen* (Berlin), December 1934, pages 380–6; (in English) *AEG Progress* (Berlin), number 2, 1935, pages 21–4.

66. Controlled Electric Impulses of the Rotating-Field Type That Are Produced by Direct Current (in French), **Albert Sornein.** *Revue Générale de l'Electricité* (Paris), volume 38, August 31, 1935, pages 291–305. Relates to the reproduction, at a distance of angular motions of various kinds.

67. Demand Totalization Using a Simplified Impulse Telemeter System, **A. R. Rutter, Paul MacGahan.** *Electric Journal*, volume 32, April 1935, pages 151–2.

68. Inductive Remote Reading (in German), **Wilhelm Geyger.** *Archiv fuer Technisches Messen* (Munich), volume 4, number 46, April 1935, sheets *T*49–*T*50, classification *V*3822.

69. Inductive Transmission of Movements (in German), **Wilhelm Geyger.** *Archiv fuer Technisches Messen* (Munich), volume 4, number 48, June 1935, sheets *T*76-*T*77, classification *V*3822.

70. New Telemetering Apparatus (in Russian), **V. O. Aroutunov.** *Izvestiya Electropromyshlennosti Slabovo Toka* (Moscow), number 4, 1935, pages 30–9.

71. Remote Measuring by Impulse Counting (in German), **P. M. Pflier.** *Archiv fuer Technisches Messen* (Munich), volume 5, number 54, December 1935, sheet *T*-162, classification *V*384.

72. Remote Measurements on Long Transmission Line (in German), **K. Riedel.** Verein Deutscher Electrotechniker *Fachberichte* (Berlin), 1935, pages 160–3.

73. Remote-Measuring System of the Frankischen Uberlandwerks, AG., Nurnberg (in German), **Andreas Kemmelmeier, Wilhelm Semmler.** *Elektrotechnische Zeitschrift* (Berlin), volume 56, February 28, 1935, pages 235–7.

74. Remote Metering and Its Application in the Power Plant Industry (in Swedish), **S. Sviden.** *Teknisk Tidskrift* (Stockholm), April 1935, pages 49–54.

75. Remote Metering Over Power Lines, **L. Dalman.** *ASEA Journal* (Västeras), volume 12, December 1935, pages 158–61; (in Swedish) *ASEA'S Tidning* (Västeras), volume 27, July 1935, pages 102–05.

76. Telemetering (in German), **Wilhelm Geyger.** *Archiv fuer Technisches Messen* (Munich), volume 5, numbers 53 and 54, November–December 1935, sheets *T*148-*T*149, *T*160-*T*161, classification *V*3821.

77. Telemetering and Totalizing, **Perry A. Borden, M. F. Behar.** *Instruments*, volume 8, August 1935, pages 207–10, 235–60, 293–6, 323–32.

78. Telemetering Totalizer (in German), **L. Brandenburger.** *Siemens Zeitschrift* (Berlin), volume 15, November 1935, pages 511–14.

79. Totalizing by Means of Impulse-Frequency Telemetry (in German), **P. M. Pflier.** *Siemens Zeitschrift* (Berlin), volume 15, September 1935, pages 457–64.

1936

80. Apparatus for Telemetering and Remote Indicating of Totalized Load (in Japanese), **Taniai-Seiiti, Okada-Keizi.** *Shibaura Review* (Tokyo), volume 15, October 1936, pages 365–71.

81. The "Baukasten" Principle (Building Up of Separate Elements) in the Design of Telemetering Devices (in Russian), **M. Gavrilov.** *Automatika i Telemekhanika* (Moscow), number 2, 1936, pages 11–19.

82. Evershed and Vignoles Distance Transmission Apparatus. *Engineering* (London), volume 141, January 17, 1936, page 58; *Engineer* (London), volume 161, January 10, 1936, pages 43, 44; *Electrician* (London), volume 116, January 10, 1936, page 37.

83. The Ferranti Repeater. *Engineer* (London), volume 162, November 13, 1936, page 525. An instrument for providing remote indication of the position of some piece of apparatus which has a range of movement between fixed limits.

84. Flow Measurements and Counting by the Pressure-Difference Method, With the Aid of Remote-Controlled Resistors and A-C Bridge Circuits (in German), **H. Lohmann.** *Siemens Zeitschrift* (Berlin), volume 16, January 1936, pages 13–17. Telemetering equipment.

85. Improvements in Telemetering Equipment (in French), **A. Iliovici.** Société Française des Electriciens *Bulletin* (Paris), volume 6, August 1936, pages 826–44; (in German) *Archiv fuer Technisches Messen* (Munich), number 76, October 1937, sheet *T*-132, classification *V*384, abstract.

86. Impulse-Compensation Method of Remote Metering (in German), **P. M. Pflier.** *Archiv fuer Technisches Messen* (Munich), volume 5, number 59, May 1936, sheets *T*58-*T*59, classification *V*384.

87. Impulse-Frequency Remote-Control Measurements (in German), **P. M. Pflier.** *Archiv fuer Technisches Messen* (Munich), volume 5, number 55, January 1936, sheets *T*1-*T*2.

88. Interesting Telemetering Installation for the Load-Dispatching Office of the Toho Denryoku Electric Power Plant, Japan (in German), **O. Bansen, K. H. Podszeck.** *Siemens Zeitschrift* (Berlin), volume 16, December 1936, pages 484–7.

89. Measuring Bridges and Comparison Circuits for Telemetering Purposes (in German), **R. Keller.** *AEG Mitteilungen* (Berlin), February 1936, pages 63–6.

90. Methods of Selection in Telecontrol Systems (in Russian), **M. I. Paretzki.** *Elektrichestvo* (Moscow), number 17, September 1936, pages 21–5.

91. Multichannel Open-Wire Lines for Telecontrol and Telemetering Purposes (in Russian), **V. A. Dubovik.** *Automatika i Telemekhanika* (Moscow), number 1, 1936, pages 35–43.

92. Neutralizing Transformer to Protect Power Station Communication, **E. E. George, R. K. Honaman, L. L. Lockrow, E. L. Schwartz.** AIEE *Transactions*, May section, volume 55, 1936, pages 524–9.

93. New Electric Transmission and Metering System for Flow Measurements (in German), **Wilhelm Geyger.** *Archiv fuer Elektrotechnik* (Berlin), volume 30, number 4, 1936, pages 240–3. Describes a remote-measuring system to be used in conjunction with flow meters.

94. New Telemetering Scheme for Intercompany Ties, **E. E. George.** *Electrical World*, volume 106, October 24, 1936, pages 3332–5. "Tennessee develops systems with versatile characteristics functioning at 5,000 cycles and at 60 cycles, also affording voice communication."

95. On a Telemetering Method With Optical Control (in Russian), **K. B. Karandeev.** *Automatika i Telemekhanika* (Moscow), number 1, 1936, pages 31–3.

96. A Photo-Telemetering System. *Electrical Review* (London), volume 118, April 3, 1936, page 498.

97. A Photo-Telemetering System. *Engineer* (London), volume 161, April 10, 1936, pages 396–7. System developed by the Automatic Electric Company, Ltd., England.

98. Power Telemetered on Pennsylvania Line, **E. H. Brown.** *Electrical World*, volume 106, February 29, 1936, pages 600–02, 664. "Energy metered at seven supply points and through one tie point and indications transmitted to dispatcher for guidance in highly important system administration."

99. Power Totalizing in Practice (in German), **W. Semmler.** *Siemens Zeitschrift* (Berlin), volume 16, September 1936, pages 366–70.

100. Remote Indicators of the Resistance Type (in German), **Wilhelm Geyger.** *Archiv fuer. Technisches Messen* (Munich),

volume 5, number 56, February 1936, sheets *T*15-*T*16, classification *V*3821.

101. Remote Metering and Automatic Load Control, **J. T. Logan.** AIEE *Transactions*, volume 55, 1936, January section, pages 40–7; discussion, August 1936, pages 891–3.

102. Remote Metering on the West Penn System, **J. G. McKinley.** *Electrical Journal*, volume 33, September 1936, pages 411–16.

103. Siemens Electric Coupling With Three-Phase Induction Motors (in French), **Pierre Satche.** *Revue Générale de l'Electricité* (Paris), volume 40, November 7, 1936, pages 595–602. Describes equipment for remote-control indication.

104. Simultaneous Distance-Control and Telemetering With PKT-5 System (in Russian), **I. V. Shavlovski.** *Elektrichestvo* (Moscow), number 20, October 1936, pages 15–22. Russian system which is claimed to be particularly useful in the dispatching service of large central stations.

105. Simultaneous Multiple Telemetering (in German), **P. M. Pflier.** *Archiv fuer Technisches Messen* (Munich), number 62, August 1936, sheet *T*-105, classification *V*387.

106. Status of Telemetering (in German), **P. M. Pflier.** *Zeitschrift Des Vereines Deutscher Ingenieure* (Berlin), volume 80, November 28, 1936, pages 1461–5. Includes a bibliography of 10 entries.

107. Supervisory Control and Remote Metering, **J. V. B. Duer.** AIEE *Transactions*, volume 55, 1936, January section, pages 70–5.

108. Technics of Measurements at Distance (in Russian), **N. F. Garkusha.** *Izvestiya Electropromyshlennosti Slabovo Toka* (Moscow), number 2, 1936, pages 46–53; number 3, pages 33–43.

109. Telemetering Applications and Operation, **L. D. Carlyon.** *Power*, volume 80, January 1936, pages 22–24. "Systems used in steam plant and water-works practice are here described and the operation of three types is explained."

110. Telemetering and Totalizing, **Perry A. Borden, M. F. Behar.** *Instruments*, volume 9, March 1936, pages 11–23, 43–8, 82–5.

111. Telemetric Systems Developed by the Research Institute of Telemechanics (in Russian), **N. F. Garkuscha.** *Elektrichestvo* (Moscow), number 17, September 1936, pages 9–17.

1937

112. Comparison of A-C and D-C Remote-Measuring Systems (in German), **H. Dallmann.** *Elektrotechnische Zeitschrift* (Berlin), volume 58, April 22, 1937, pages 423–4.

113. Compensating Method of Telemetering (in Russian), **N. F. Garkusha, J. G. Karnilov.** *Izvestiya Electropromyshlennosti Slabovo Toka* (Moscow), number 1, January 1937, pages 23–8.

114. Electrically Operated Flow Meter. *Instruments*, volume 10, May 1937, page 124.

115. Evershed–Midworth Telemeter System. *Engineer* (London), volume 163, January 8, 1937, pages 44–5; *Electrician* (London), volume 118, January 15, 1937, pages 68–9.

116. Example of Telecontrol (in French), **André Pux.** *Electricité* (Paris), number 32, May 1937, pages 195–200. Telemetering equipment in a French central station.

117. High-Frequency Telemetering Equipment on an Extensive High-Voltage Network (in German), **K. Riedel.** *Siemens Zeitschrift* (Berlin), volume 17, January 1937, pages 12–18.

118. Impulse Time Telemetering Methods (in German), **L. Brandenburger.** *Archiv fuer Technische Messen* (Munich), number 68, February 1937, sheets *T*-19-*T*-20, classification *V*384.

119. Intermittent Multiple Transmission of Measurements (in German), **P. M. Pflier.** *Archiv fuer Technisches Messen* (Munich), number 67, January 1937, sheets *T*9-*T*10, classification *V*387.

120. Limitation of Transmission Distance for Measurements by Ordinary Instruments (in German), **P. M. Pflier.** *Archiv fuer Technisches Messen* (Munich), number 72, June 1937, sheets *T*71-*T*74, classification *V*381.

121. Long-Distance Transmission and Centralization of Power and Energy Measurements for Plants Feeding Government-Operated Electrified Railway Lines (in Italian), **G. Musso.** *L'Elettrotecnica* (Milan), volume 24, January 10, 1937, pages 6–16; January 25, 1937, pages 46–9.

122. Modern and Appropriate Requirements in Telemetering Equipment (in German), **W. Fleischer.** Verein Deutscher Electrotechniker *Fachberichte* (Berlin), volume 9, 1937, pages 170–3.

123. Null-Method Flow Measuring and Integrating Equipment. *Instruments*, volume 10, February 1937, page 35.

124. Pneumatic Telemetering, **C. B. Moore, B. Coleman.** *Instruments*, volume 10, September 1937, pages 242–3, 248; *Mechanical Engineering*, volume 60, April 1938, pages 332–3. Abstract.

125. Power-Line Carrier Telemeter (in Japanese), **Schigyo-Iwane, Hioki-Takashi.** *Shibaura Review* (Tokyo), April, 1937, volume 16, pages 139–45.

126. The Remote Indication of Meter Readings, **C. Myers.** General Electric Company *Journal* (London), volume 8, August 1937, pages 201–05.

127. A Syllabus of Telemetering Applications, **L. D. White.** *General Electric Review*, volume 40, May 1937, pages 254–5.

128. Telemetering Instruments and Devices (in German), **H. V. Keller.** *Zeitschrift Des Vereines Deutscher Ingenieure* (Berlin), volume 81, June 26, 1937, pages 777–82.

129. A Telewatt Metering System. *Engineer* (London), volume 163, March 12, 1937, pages 314–15. English equipment for totalizing, over any distance, the output of a number of generators or stations.

130. Transmission and Centralization of Power and Energy Measurements on the Italian State Railway (in German). *Siemens Zeitschrift* (Berlin), volume 17, November 11, 1937, pages 550–8.

1938

131. Ammeter Measures Direct Current Two Miles Away, **F. S. Stickney.** *Electrical World*, volume 110, September 24, 1938, pages 884–6.

132. Carrier-Current Telemeter, **S. Jimbo, T. Ito.** *Electrotechnical Journal* (Tokyo), volume 2, February 1938, pages 32–5. "Describes a new system of carrier current telemetering in which the impulse-current method with a photo electric cell is utilized."

133. Centralized Control of Frequency and Power Flow in the Paris Area (in French), **J. Fallou.** *Revue Générale de l'Electricité* (Paris), volume 43, January 15, 1938, pages 67–77.

134. Instruments and Methods of Telemetering (in German), **H. Kramm.** *Zeitschrift fuer Fernmeldetechnik* (Munich), volume 19, January 1938, pages 1–4.

135. Load Totalization, **E. J. Boland.** *General Electric Review*, volume 41, June 1938, pages 282–7.

136. New Telemetering Equipment (in French), **J. Pelpel.** Société Française des Electriciens *Bulletin* (Paris), volume 8, October 1938, pages 933–47. Pilot-wire and carrier-wave methods.

137. Pneumatic Telemetering System by the Bristol Company. *Canadian Engineer* (Toronto), volume 74, June 28, 1938, page 18.

138. Siemens Remote-Metering Plant (in German). *Archiv*

fuer Technisches Messen (Munich), number 82, April 1938. sheet *F6*, classification *V384*.

139. Some Improvements in Practical Telemetering (in German), **J. Sorge.** Verein Deutscher Electrotechniker *Fachberichte* (Berlin), volume 10, 1938, pages 111–13.

140. Superposing Remote Metering and Counting Impulses Upon Telephone Lines (in German), **G. Kamphausen.** *Siemens Zeitschrift* (Berlin), volume 18, February 1938, pages 46–51. The use of impulses in the frequency range of 16 to 225 cycles.

141. Telemetering, **Paul MacGahan.** *Electric Journal*, volume 35, March 1938, pages 113–16. "The five basic telemetering systems are briefly reviewed in this article." Includes a bibliography of 16 items.

142. Tie-Line Control With Frequency Bias, **E. L. White.** *Electrical West*, volume 80, June 1938, pages 132–4. Includes description of General Electric photoelectric telemeter.

1939

143. Carrier Telemetering Simplifies Dispatching, **H. L. Durgin.** *Electrical World*, volume 112, December 16, 1939, pages 1732–3, 1742. Illustrated description of "Metameter" system used on lines of the Central Vermont Public Service Corporation.

144. Electrothermic Principle of Totalizing Electrical Energy and its Long Distance Transmission (in French), **D. J. L. Coninck-Westenberg.** Société Belge des Electriciens *Bulletin* (Brussels), volume 55, May 1939, pages 298–327. "Deals with the Lincoln thermal wattmeter and its application to remote indication of power."

145. High-Frequency Telephony and Remote-Measurement Apparatus for 100-Kv Cable Installations (in German), **R. Deppe, K. H. Podszeck.** *Siemens Zeitschrift* (Berlin), volume 19, July 1939, pages 309–12. Transmitters and receivers adapted for high-frequency telephony and remote-measurement between works making use of the same 100-kv power line.

146. Impulse Transmitter for Telemetering (in German), **L. Brandenburger.** *Siemens Zeitschrift* (Berlin), volume 19, January 1939, pages 42–5.

147. The Metameter System of Telemetering, **F. B. Bristol, G. S. Lunge.** *General Electric Review*, volume 42, November 1939, pages 466–72.

148. Phase-Angle Control of System Interconnections, **R. E. Pierce, B. W. Hamilton.** AIEE *Transactions*, volume 58, 1939, March section, pages 83–92.

149. Remote Measurement by the Amplitude-Modulation Method, **T. Tomituka.** *Electrotechnical Journal* (Tokyo), volume 3, April 1939, pages 79–80. "Experimental work is described and a system of remote indication by carrier current detailed."

150. Telemeter Steam and Electricity on Indianapolis System, **T. W. Ayton.** *Electrical World*, volume 112, August 26, 1939, pages 584–6, 642. "Effective balancing of industrial steam load with steam requirements for generation demands indication of both quantities at dispatcher's office. Describes the system used and gives reasons for its selection."

151. Telemetering Device for Hydro Plants. *Electrical World*, volume 111, June 17, 1939, page 1854.

152. Water Waste Successfully Eliminated in Ontario Municipality; Installation of Metameter System of Telemetering. *Canadian Engineer* (Toronto), volume 77, August 22, 1939, pages 4–5, 23.

153. Why Telemetering? **G. S. Lunge.** *General Electric Review*, volume 42, April 1939, pages 150–59. "Fields of service, types of equipment, applications, selection of type, convenience, and economy."

1940

154. Automatic Water-Stage Transmitters, **Maurice E. Kennedy.** *Communications*, volume 20, February 1940, pages 10–11. "A device to measure the water elevation in remote mountain streams and to transmit the information by radio to a receiving tape on the particular dam being fed by the measured streams."

155. Carrier Telemetering With the Metameter, **G. S. Lunge.** *General Electric Review*, volume 43, August 1940, pages 336–43.

156. Everett Edgcumbe Auto Repeater System of Distant Indication. *Engineer* (London), volume 169, April 5, 1940, page 322.

157. A Follow-Up Telemetering System. *Electronics*, volume 13, September 1940, pages 47–8, 50. Esterline-Angus system.

158. Telemeter Water-Level Record, **Reginald Trautschold.** *Electrical World*, volume 114, December 28, 1940, page 1952.

159. Telemetering Scheme for Generating Stations, **Ludwig F. Lischer.** *Electrical World*, volume 113, March 9, 1940, page 770.

160. Unusual Application of a General-Electric Torque Balance Watt Telemeter; Obtaining Hourly Integration of Power Interchange, **Charles Wasserman.** *Instruments*, volume 13, August 1940, pages 219–20.

161. Water Level Indicator, **L. A. Ware.** *Electronics*, volume 13, March 1940, pages 23–5. An application of a bridge-controlled thyratron follow-up system.

162. Telemetering, Supervisory Control, and Associated Circuits, AIEE committee report. AIEE *Transactions*, volume 60, 1941, pages 1411–34.

1941

163. Averting Several Weeks' Delay in Starting Up New Defense Plant, **James L. Watson.** *Instruments*, volume 14, April 1941, pages 101–102. An emergency telemetering installation.

164. Industrial Instruments for Measurement and Control, **Thomas J. Rhodes.** McGraw-Hill Publishing Company, Inc., N. Y., N. Y., Telemetering, 1941, pages 356–73.

165. A New High-Speed Thermal Wattmeter, **John H. Miller.** AIEE *Transactions*, volume 60, 1941, January section, pages 37–40. Includes a reference list of 16 items.

166. Possibilities and Methods of Extending a Carrier-Current Relay Channel to Other Uses, **R. M. Smith, S. L. Goldsborough.** AIEE *Transactions*, volume 60, 1941, January section, pages 23–7.

167. Telemetering Used to Good Advantage on California Gas Line, **T. P. Sanders.** *Oil and Gas Journal*, volume 40, September 18, 1941, page 136.

Automatic and Remote Controlled Switches and Switchgear

1930

1. Automatic Reclosing Breakers Reduce Outage Time, **E. R. Stauffacher.** *Electrical World*, volume 95, May 3, 1930, page 892.

1931

2. Automatic Leakage Current Switches, **T. C. Gilbert.** *Electrician* (London), volume 106, May 8–June 12, 1931, pages 687, 718–19, 756, 786, 814, 849.

3. Automatic Live-Line Selection, **C. W. Jones.** *Electrical World,* volume 98, November 14, 1931, page 876.

4. Automatic Operation at the Cleveland Union Terminals, **F. E. Jaquay.** *General Electric Review,* volume 34, June 1931, pages 350–6.

5. Automatic Switching Equipment for Motor-Generator Sets at the Campbell Works of the Youngstown Sheet and Tube Company, **C. M. Myers, J. H. Graft.** *General Electric Review,* volume 34, July 1931, pages 431–5.

6. Automatic Switching Equipment for Synchronous Motor-Generators, **D. C. Hoffman.** *Power Plant Engineering,* volume 35, February 1, 1931, pages 202–05.

7. Automatic Switching Equipment in Industry, **F. P. Brightman.** *General Electric Review,* volume 34, May 1931, pages 284–7.

8. Metal-Enclosed Automatic Switchgear for Anthracite Mines, **J. T. Jennings, R. S. Redmon.** *General Electric Review,* volume 34, June 1931, pages 388–93.

9. Reclosing of Circuit-Breakers in Large D-C Systems (in German), **C. E. Dahl.** *AEG Mitteilungen* (Berlin), June 1931, pages 347–53.

10. Some Examples of Switchgear for Automatic Reclosing of A-C Feeders (in French), **M. J. Cade.** *Revue d'Electricité et de Mécanique* (Paris), volume 3, November, December 1931, pages 44–6.

1932

11. Automatic Air-Break Switch Reduces Outage Time, **R. E. Greene.** *Electrical World,* volume 100, October 15, 1932, pages 541–2.

12. Automatic Change-Over of a Substation to a Reserve Station in Case of Voltage Failure (in German), **A. Hug.** *AEG Mitteilungen* (Berlin), January 1932, pages 26–9.

13. Automatic Reclosing Duty Cycles for Oil Circuit Breakers, **W. F. Sims.** National Electric Light Association *Bulletin,* volume 19, November 1932, page 696.

14. Automatic Synchronizing Switchgear (in German), **H. Wierer.** *Siemens Zeitschrift* (Berlin), volume 12, November, pages 381–5; December 1932, 434–6.

15. Automatic Synchronizing Switchgear for A-C Networks (in German), **A. Gantenbein.** Schweizerischer Elktrotechnischer Verein *Bulletin* (Zurich), volume 23, December 23, 1932, pages 677–83.

16. Industrial Plant Synchronous Condensers Automatically Controlled, **F. P. Brightman.** *Power,* volume 75, April 12, 1932, pages 542–4.

17. Metal-Clad Switchgear, Automatic Protection, and Remote Control, With Particular Reference to Developments During the Last Seven Years, **H. W. Clothier.** Institution of Electrical Engineers *Journal* (London), volume 71, August 1932, pages 285–373; discussion, volume 71, October 1932, pages 651–62; volume 75; November 1934, pages 652–9.

18. Service Continuity Promoted by Rapid Breaker Reclosure, **Robert Treat, H. C. Verwoert.** *Electrical World,* volume 100, August 6, 1932, pages 172–5; discussion, **E. E. George,** volume 100, October 29, 1932, page 606.

19. Service Restoration Expedited After Line Trouble, **L. W. Wyss.** *Electrical World,* volume 100, August 27, 1932, pages 284–5.

20. Time Delay Under-Voltage Mechanism on Electrical Control Apparatus, **Edwin M. Clapp.** National Electric Light Association *Bulletin,* volume 19, November 1932, pages 683–5.

21. Use of Multi-Pole Switches in Automatic Switching Plants (in German). *AEG Mitteilungen* (Berlin), April 1932, pages 136–9.

22. Utilization of Automatic Throwover Apparatus for Street Vaults and Customers' Substations Where Automatic Transfer of Load to a Standby Circuit Is Required, **C. D. Bidwell.** *Electrical West,* volume 68, May 15, 1932, pages 347–51.

1933

23. Automatic Change-Over and Reclosing Switchgear, **W. Fenwick.** South African Institute of Electrical Engineers *Transactions* (Johannesburg), volume 24, September 1933, pages 216–28.

24. Automatic Reclosing Circuit Breakers. *Engineer* (London), volume 156, October 27, 1933, page 414.

25. Automatic Reclosing Cycles for Oil Circuit Breakers and Practices Regarding Relative Interrupting Capacity Ratings on Circuit Breaker Application. Progress Report, Edison Electric Institute *Bulletin* December 1933, pages 276–9.

26. Automatic Rectifier Operation in the "Burg" Theatre Vienna (in German), **H. von Bertele.** *Elektrotechnische Zeitschrift* (Berlin), volume 54, April 20, 1933, pages 371–3. Description of the automatic switchgear employed.

27. Automatic Switching for System Ties, **E. B. Ellett.** *Electric Journal,* volume 30, July 1933, pages 295–7.

28. High-Speed Circuit Breakers: their application to remote-controlled traction substations, **H. C. Harris.** *Electrical Review* (London), volume 112, April 14, 1933, page 516.

29. Keeping the Line in Service by Rapid Reclosing, **S. B. Griscom, J. J. Torok.** *Electric Journal,* volume 30, May 1933, pages 201–04.

30. A New Automatic Across-the-Line Switch. *Power Plant Engineering,* volume 37, November 1933, page 491.

31. Pole-Type Switchgear, Three-phase automatic switches for operation under load. *Electrician* (London), volume 111, November 10, 1933, page 582.

32. The Principle of Condenser Discharge Applied to Central-Station Control Problems, **F. H. Gulliksen.** AIEE *Transactions,* volume 52, 1933, pages 232–9.

33. 1933 Progress Report on Operating Experience With Reclosing Circuit Breakers, **E. S. Fields.** Edison Electric Institute *Bulletin,* volume 1, December 1933, pages 276–9.

34. Safety Devices and Automatic Switches (in German), **Paul O. Schneider.** World Power Conference *Transactions,* Sectional Meeting Scandinavia (Stockholm), volume 5, 1933, pages 638–49. For low-voltage systems.

35. Sectionalizing Switches Automatically Maintain Service, **H. L. Sampson.** *Electrical World,* volume 101, April 29, 1933, page 545.

1934

36. Automatic Reclosing of Oil Circuit Breakers, **A. E. Anderson.** AIEE *Transactions,* volume 53, 1934, January section, pages 48–53; discussion, March section, pages 466–7; April section, pages 614–15. *Power Plant Engineering,* volume 38, April 1934, pages 192–4.

37. Automatic Section Switches for D-C Railway Systems (in German), **B. Fleck.** *Elektrische Bahnen* (Berlin), volume 10, March 1934, pages 65–7.

38. A Compensated Automatic Synchronizer, **H. T. Seeley.**

AIEE *Transactions*, volume 53, 1934, June section, pages 960–8.

39. Fast Reclosing Service at Lower Cost, **W. L. Garlington.** *Electrical World*, volume 103, February 10, 1934, pages 226–7.

40. Faster Reclosing Breakers Needed, **J. T. Logan.** *Electrical World*, volume 103, April 21, 1934, pages 571–2.

41. Many Interruptions to Electric Power Supply Are Avoidable—Eliminating Delays in Making Reclosures, **Robert Treat.** *General Electric Review*, volume 37, April 1934, pages 162–4.

42. The Mercury Reclosing Device for Automatically Reclosing Circuit Breakers, **A. E. Anderson.** *General Electric Review*, volume 37, October 1934, pages 462–7.

43. Multiple Lightning Strokes, **K. B. McEachron.** *Electrical World*, volume 53, December 1934, pages 1633–7. Of value to the designer of protective equipment.

44. Oil Recloser for Distribution, **R. M. Spurck, D. K. Blake.** *Electrical World*, volume 104, October 27, 1934, pages 730–1, 786.

45. Outdoor Metal-Clad Switchgear and Centrovisory Control Equipment. *Engineer* (London), volume 158, August 17, 1934, pages 170–2; *Electrician* (London), volume 113, August 10, 1934, pages 185–6; *Electrical Review* (London), volume 115, August 10, 1934, page 186.

46. Reclosing Devices for Circuit Breakers Equipped for Automatic Tripping, **E. Kronauer.** *Brown Boveri Review* (Baden), volume 21, November 1934, pages 191–4.

1935

47. A-C Control for Instantaneous Reclosing Circuit Breakers, **R. L. de Loach.** *Power Plant Engineering*, volume 39, May 1935, pages 289–90.

48. Crompton Parkinson Auto-Reclose Mechanism. *Electrician* (London), volume 115, December 27, 1935, page 808. Abstract of New Equipment and appliances.

49. Further Development in Oil-Blast Circuit Breakers, **D. C. Prince.** *General Electric Review*, volume 38, September 1935, pages 415–21. Includes consideration of circuit-reclosing equipment.

50. Immediate Automatic Reclosing of Circuit Breakers, **W. M. Emmons.** *Electric Journal*, volume 32, March 1935, pages 114–18.

51. Immediate Initial Reclosure of Oil Circuit Breakers, **D. C. Prince, A. E. Anderson.** *General Electric Review*, volume 38, June 1935, pages 258–62.

52. Immediate Reclosure of 110-Kv Breakers, **J. T. Johnson, Jr., J. W. Graff.** *Electrical World*, volume 105, August 31, 1935, pages 2101–03.

53. The Oil Circuit Recloser and Its Operation, **L. S. Hobson.** *General Electric Review*, volume 38, November 1935, pages 511–13.

54. One-Cycle Carrier Relaying Accomplished, **Philip Sporn, C. A. Muller.** *Electrical World*, volume 105, October 12, 1935, pages 2434–6.

55. A Reclosing Circuit Breaker. *Engineer* (London), volume 159, June 28, 1935, pages 677–8.

56. Reclosing Equipment for Medium- and Low-Voltage Circuits, **A. C. Abbott, E. Gray-Donald.** *Electrical News and Engineering* (Toronto), volume 44, July 1, 1935, pages 26–7.

57. Relay Systems: Theory and Applications, **I. T. Monseth, P. H. Robinson.** McGraw-Hill Book Company, Inc., New York, N. Y., 1935, 547 pages. Automatic reclosing of oil circuit breakers, pages 418–23.

58. Results With Quick Reclosure of 110-Kv Breakers, **J. T. Johnson, Jr., J. W. Graff.** *Electrical World*, volume 105, September 14, 1935, pages 2214–16.

59. 32-Cycle Reclosure of 110-Kv Breaker, **J. H. Paget.** *Electrical World*, volume 105, March 2, 1935, page 512.

60. Type ETA Circuit Recloser With Totalizer, for Automatic Reclosing of Circuit Breakers (in French). Ateliers de Construction Electrique de Charleroi (Charleroi), April–June 1935, pages 49–50. Short description of Ateliers de Construction Electrique equipment.

1936

61. Automatic Reclosers, Abstract of A Half Century of Engineering Progress, **H. W. Cope.** *Electric Journal*, volume 33, January 1936, page 26.

62. Automatic Reclosing Mechanism for Oil Circuit Breakers (in French). Ateliers de Construction Electrique de Charleroi (Charleroi), number 150, April–June 1936, pages 77–82.

63. Automatic Switching Installations for Mercury-Arc, Glass-Bulb Rectifiers (in German), **B. Fleck.** *Elektrotechnik und Maschinenbau* (Vienna), volume 54, August 23, 1936, pages 397–401.

64. Carrier Relaying and Rapid Reclosing at 110 Kv, **R. E. Pierce, R. E. Powers, E. C. Stewart, G. E. Heberlein.** AIEE *Transactions*, volume 55, 1936, October section, pages 1120–4.

65. Many Features of Automatic Switchgear Applicable to Attended Stations, **H. Bany.** *General Electric Review*, volume 39, August 1936, pages 388–93.

66. Repeated Automatic Starting, **R. Davies.** *Electrical Review* (London), volume 118, April 17, 1936, page 557.

67. Some New Devices for the Remote Control of Oil Circuit Breakers (in French). Ateliers de Construction Electrique de Charleroi (Charleroi), April–June 1936, pages 77–82. Ateliers de Construction Electrique control equipment.

1937

68. Automatic Control of Pumping Stations (in French), **L. Besnard.** *Revue Générale de l'Electricité* (Paris), volume 42, September 11, 1937, pages 335–49. Detailed, illustrated description of the electric control equipment.

69. Auto-Reclose Circuit Breakers. *Electrician* (London), volume 119, October 15–22, 1937, pages 439, 471.

70. A New Service Restorer, **E. F. Sixtus, W. R. Nodder.** AIEE *Transactions*, volume 56, 1937, January section, pages 180–2, 152. An automatic restorer of the Pacific Electric Manufacturing Corporation.

71. Outdoor High-Voltage Switchgear (book), **R. W. Todd, W. H. Thompson.** Isaac Pitman and Sons, London, England, New York, N. Y., 1937, 436 pages. Automatic reclosing, pages 422–3.

72. Rapid Elimination of Faults and Ultrahigh-Speed Reclosing of High-Tension Transmission Lines (in French), **Philip Sporn, D. C. Prince.** International Conference on Large High-Voltage Electric Systems (CIGRE, Paris), volume 3, 1937, Report 339.

73. Recent Developments in Low-Voltage Switchgear (in German), **D. Muller-Hillerbrand.** *Siemens Zeitschrift* (Berlin), volume 17, October 1937, pages 505–16.

74. Reclosers Sectionalize Distribution Lines, **E. H. Beckert.** *Electrical World*, volume 107, April 10, 1937, pages 1225, 1278, 1280.

75. Sectionalizing Power by Automatic Circuit Breakers, **John T. Parker.** *Mining Congress Journal*, volume 23, September 1937, pages 64–5, 70.

76. The Ultrahigh-Speed Reclosing Explusion Oil Circuit-Breaker, **A. C. Schwager.** AIEE *Transactions*, volume 56, 1937, August section, pages 968–70.

77. Ultrahigh-Speed Reclosing of High Voltage Transmission Lines, **Philip Sporn, D. C. Prince.** AIEE *Transactions*, volume 56, 1937, January section, pages 81–90, 100.

1938

78. Automatic Circuit Breakers for Scraper-Hoist Motors, **J. M. Leonard.** *Engineering and Mining Journal*, volume 139, January 1938, page 47.

79. Automatic Low-Voltage Switchgear As Used in Mines (in German), **E. Lewien.** *Elektrizitat Im Bergbau* (Munich), volume 13, February 1938, pages 15–18.

80. Automatic Reclosing Equipment for Alternating-Current Distribution Circuits Having Potentials Up to 17,500 Volts (in French), **M. J. Dufrov.** *Revue d'Electricité et de Mécanique* (Paris), August, October 1938, pages 35–40.

81. Clearing Temporary Faults on Interconnected Lines by Means of Extra-High Speed Circuit Breakers (in French), **M. P. Ailleret.** Société Française des Electriciens *Bulletin* (Paris), volume 8, April 1938, pages 341–8.

82. New Small Switchgear (in German), **H. Remy.** *AEG Mitteilungen* (Berlin), volume 3, 1938, pages 156–8. Automatic equipment.

83. Recent Developments in Apparatus for the Interruption of High-Tension Circuits (in French), **M. J. Saint-Germain.** Société Française des Electriciens *Bulletin* (Paris), volume 8, January 1938, pages 63–96. Considerable attention to automatic features.

84. Reclosing Cutouts for Economy and Service, **Edward Allen.** *Electric Light and Power*, volume 16, October 1938, pages 34–7.

85. Up-to-Date Protection for Yesterday's Circuits, **E. H. Bancker, E. H. Beckert.** *Electric Light and Power*, volume 16, June 1938, pages 76–9. Includes a brief discussion of automatic reclosing.

86. What Time Delay for Automatic Reclosure? **G. F. Lincks.** *Electrical World*, volume 110, December 31, 1938, pages 1822–3, 1862–3, 1865.

1939

87. Automatic Control of Plant Capacitors. *Electrical World*, December 2, 1939, pages 1626–8.

88. Automatically Controlled Shunt Capacitors, **R. V. Sanford,** *Electrical World*, July 15, 1939, pages 72–4.

89. Automatic Recloser for Circuit Breakers (in Swedish), **G. Dahlby.** *ASEA'S Tidning* (Västeras), volume 31, September–October 1939, pages 146–7.

90. Capacitors Switched by Automatic Unit, **R. V. Sanford.** *Electrical West*, volume 83, October 1939, pages 40–1.

91. Considerations on the Use of Quick-Acting Circuit Breakers With Automatic Reclosing in Overhead Lines, **O. Naef.** *Schweizerischer Elektrotechnischer Verein* (Zurich), volume 30, December 6, 1939, pages 761–5.

92. Experience With High-Speed Fault Clearing and With Ultrahigh-Speed Reclosing of High-Voltage Transmission Lines, **Philip Sporn, C. A. Muller.** International Conference on Large High-Voltage Electric Systems (CIGRE, Paris), volume 3, Report number 322, 1939, pages 1–22.

93. Experience With Ultrahigh-Speed Reclosing of High-Voltage Transmission Lines, **Philip Sporn, C. A. Muller.** AIEE *Transactions*, volume 58, 1939, December section, pages 625–36.

94. Fundamentals of Automatic Reclosing Circuit Breaker Application, **Donald J. Baker.** *Mining Congress Journal*, volume 25, July 1939, pages 35–6.

95. High Tension High-Speed Circuit Breakers and Their Application for Ultrarapid Rupture and Reclosing (in French), **O. Mayr.** International Conference on Large High-Voltage Electric Systems (CIGRE, Paris), volume 1, report number 121, 1939, pages 1–16.

1940

96. Automatic Reclosing Device for Feeder Switches, **G. Dahlby.** *ASEA Journal* (Västeras), volume 17, February 1940, pages 30–1. Allmanna Svenska Elektriska Aktiebolaget Recloser.

97. Automatic Switches Improve Reliability. *Electrical World*, volume 114, November 2, 1940, page 1342.

98. Automatic Switching Multiples Capacitor Effectiveness, **W. H. Cuttino, J. E. Hobson.** *Electric Light and Power*, volume 18, October 1940, pages 40–3.

99. Improvement of Continuity of Service on Rural Grid Systems; Automatic Reclosing of Circuit Breakers on High-Voltage Lines (in German), **A. Roth.** Schweizerischer Elektrotechnischer Verein *Bulletin* (Zurich), volume 31, September 18, 1940, pages 414–16.

100. Inertia Relay "Anticipates" to Facilitate Reclosure, **J. T. Logan, J. H. Miles.** *Electrical World*, volume 113, April 6, 1940, pages 1061–4.

1941

101. An Automatically Reclosing Breaker for Co-Ordinating Distribution Systems, **H. L. Rawling, J. M. Wallace.** AIEE *Transactions*, volume 60, 1941, December section, pages 1021–4.

102. Develop Automatic 15-Kv Underground Transfer Switch, **P. S. Timberlake.** *Electric Light and Power*, volume 19, September 1941, pages 55–6.

103. Factors Contributing to Improving Electric Service by Means of High-Speed Switching and Utilization of Stored Energy, **J. T. Logan, J. H. Miles.** AIEE *Transactions*, volume 60, 1941, December section, pages 1012–16.

104. Five Years' Experience With Ultrahigh-Speed Reclosing of High-Voltage Transmission Lines, **Philip Sporn, C. A. Muller.** AIEE *Transactions*, volume 60, 1941, May section, pages 241–5; discussion, pages 690–4.

105. A Novel Reclosing Relay, **P. O. Bobo.** AIEE *Transactions*, volume 60, 1941, December section, pages 1041–5.

106. Ten Years of Progress in Circuit Interrupters, AIEE Committee on protective devices. *Electrical Engineering*, volume 60, November 1941, pages 523–37.

107. Reclosing Breakers or Reclosing Fuses—Which? **H. A. P. Langstaff.** *Electrical World*, volume 115, March 22, 1941, pages 974–7.

Section E

Automatic Features of Generating Stations Using Fuels

1931

1. Automatic Control in Steam Power Plants (in German) **H. Schult.** Verein Deutscher Electrotechniker *Fachberichte* (Berlin), 1931, pages 122–4.

2. Automatic Generators Prevent Power Outages, **D. C. Hoffman.** *Power*, volume 73, May 12, 1931, page 741.

1932

3. Automatic Diesel Power Plant for New York Office Building. *Diesel Power*, volume 10, August 1932, page 330.

4. Automatic Operation of Standby Diesel Plants (in German), **F. Schneider.** *AEG Mitteilungen* (Berlin), January 1932, pages 6–10.

5. Automatic Regulators Aid Process-Steam Production, **F. A. Byles.** *Power*, volume 76, October 1932, pages 179–81.

6. Automatic-Starting Diesel Plants. *Gas and Oil Power* (London), volume 27, December 1, 1932, pages 259–60.

7. Fully Automatic Emergency Diesel Generating Sets. *AEG Progress* (Berlin), November 4, 1932, pages 70–1.

1933

8. Improving Service With Automatic Control (Alameda Street Station of the Los Angeles Gas and Electric Corporation). *Electrical World*, volume 102, August 5, 1933, pages 182–4.

9. Operating Safety in Power Plants Through the Use of Automatic Steam Turbines (in German), **A. Sennefelder.** *AEG Mitteilungen* (Berlin), March 1933, pages 29–32.

10. Slotted Switchboards: A New Type for Automatic Power Plants (in German), **J. Eisert.** *Siemens Zeitschrift* (Berlin), volume 13, November–December 1933, pages 342–7.

11. The Strong Automatic Control for Diesel Plants. *Diesel Power*, volume 11, January 1933, pages 29, 31, 33, 35.

1935

12. Small Steam Turbine Station Operates Entirely Unattended, **Xenophon D. Ides.** *Power Plant Engineering*, volume 39, December 1935, pages 684–9.

1936

13. Automatic Equipment for the Unattended Operation of Generating and Converting Stations, **Hans Eger.** *ASEA Journal* (Västerås), volume 13, January 1936, pages 6–13.

14. Engineering Fundamentals of the Five Main Systems of Supervisory Protection for Generators (in German), **Ernst Bopp.** *Siemens Zeitschrift* (Berlin), volume 16, October 1936, pp. 405–13.

1937

15. Automatic Diesel Plant Confounds the Rate Maker. *Diesel Power*, volume 15, August 1937, pages 584–5. Short description of a private generating plant.

16. Automatic Diesel Plant—Is It Practical? **George B. Bailey.** *Power Plant Engineering*, volume 41, February 1937, pages 88–90.

17. Automatic Power Station Equipment in South Africa, **J. W. Gibson.** General Electric Company *Journal* (London), volume 8, November 1937, pages 288–94.

18. Automatically Started and Stopped Diesel Engine-Driven Generator Units, **G. Deri.** *Revue Général de l' Electricité* (Paris), April 17, 1937, pages 499–504.

19. Diesels for Automatic Standby, **H. R. Artman.** *Power Plant Engineering*, April 1937, pages 216–18.

1938

20. Automatic Control Features Generating Plant Operation, **H. Bany.** *Southern Power Journal*, volume 56, March 1938, pages 37–41; June 1938, pages 55–8; September 1938, pages 44–7; November 1938, pages 35–7.

21. Automatic Diesel-Electric Stand-by Plants. *Gas and Oil Power* (London), volume 33, October 1938, pages 247–8. Particulars of Brown Boveri equipment.

22. Automatic Diesel-Electric Stand-By Plants, **W. Kissling.** *Brown Boveri Review* (Baden), volume 25, July 1938, pages 149–51.

23. Modern Tendencies in the Regulation of Central Stations and Lines That Operate in Parallel (in Italian), **A. Barbagelata.** *L'Elettrotecnica* (Milan), volume 25, April 25, 1938, pages 254–63. Devices and methods for the automatic regulation of such equipment.

24. Recent Developments in Remote and Automatic Control of Power Plants and Substations (in French), **N. Vadja.** Société Belge des Electriciens *Bulletin* (Brussels), volume 54, February 1938, pages 66–77, March 1938, pages 122–40. Lays special emphasis on hydro plants.

25. The Thermal Supervisory Installation for the Emergency Equipment of Simmering Power Plant, Vienna (in German), **Rudolf Mokesch.** *Zeitschrift des Vereines Deutscher Ingenieure* (Berlin), volume 82, April 9, 1938, pages 433–9. Illustrated description of automatic-control equipment for boilers and turbines.

1939

26. The Field for Automatic Diesels, **E. Wanamaker.** *Diesel Progress*, volume 5, July 1939, pages 34–6.

1940

27. Automatic Variable Speed Diesel Electric Plants, **George B. Bailey.** *Diesel Progress*, volume 6, June 1940, pages 45–7. Tecomatic control.

28. Development of Automatic Control for Emergency Diesel-Driven Generators (in German), **Hugo Stossinger.** *Elektrotechnische Zeitschrift* (Berlin), volume 61, March 14, 1940, pages 269–71.

29. Full Automatic Diesel-Electric Emergency Sets (in German), **A. Schoen.** *Elektrotechnische und Maschinenbau* (Vienna), volume 58, February 16, 1940, pages 77–82.

30. Unattended Electric Power Plant. *Engineering* (London), volume 149, January 26, 1940, pages 86–7; *Engineer* (London), volume 169, February 9, 1940, pages 130–1. Oil engine driven plant in South Africa.

1941

31. Automatic Diesel Plants. *Diesel Power*, volume 19, August 1941, pages 687–93. Typical designs, field of application, use of overrunning clutches.

32. Automatically-Controlled Rural Electric Plant, **Cecil P. Molyneux.** *Diesel Power*, volume 19, August 1941, pages 659, 662, 664, 666. The plant of the Washington Electric Cooperative, Inc., in East Montpelier, Vt.

33. High-Pressure Functioning Relies on Automatic Controls. **Sigmund N. Fiala.** *Electrical World*, volume 116, October 18, 1941, pages 1251–5. Boiler, feedwater, turbine, and condensate controls at Twin Branch plant of the Indiana and Michigan Electric Company.

34. Single-Unit Plant Designed for One-Man Operation, **W. P. Venable.** *Electrical World*, volume 116, September 6, 1941, pages 710–13, 786–7. The Bluffs plant of the Western Public Service Company, Scottsbluff, Nebr.

Section F

Automatic Boiler and Combustion Control

1931

1. Automatic Boiler Control As A Safety Factor, **W. H. Monahan.** *Power*, volume 73, June 23, 1931, page 995.

2. Automatic Combustion Control, **F. Aschner.** *Engineering and Boiler House Review* (London), volume 44, April–May 1931, pages 670, 672, 674, 702–04. AEG Askania System.

3. Automatic Combustion Control, **C. H. Sanderson, E. B. Ricketts.** AIEE *Transactions*, volume 50, 1931, pages 1378–87. *Power*, volume 74, July 21, 1931, pages 100–01, abstract; *World Power* (London), volume 17, March 1932, pages 201–02, abridged reprint.

4. Automatic Combustion Control for Boilers, **S. J. Clifton.** Junior Institution of Engineers *Journal* and Record of *Transactions* (London), volume 42, December 1931, pages 127–68.

5. Automatic Regulation of Boilers (in French), **G. Poux.** *Le Génie Civil* (Paris), volume 98, June 27, 1931, pages 640–3.

6. Combustion Control Co-Ordinates New Power Plant, **K. R. Warrington.** *Combustion*, volume 3, December 1931, pages 20–2.

7. Combustion-Control Equipment, System of Automatic Boiler Control With Complete Electrical Operation. *Electrical Review* (London), volume 109, August 21, 1931, pages 283–4.

32. Automatic Regulator Embodies New Stabilizing Principle. *Power*, volume 78, September 1934, pages 504–05. Fluid-operated device for control of combustion processes, pressure, speed, volume, temperature, liquid levels, and air flow.

33. Automatic Systems of Heat Regulation in Boilers (in French). *Génie Civil* (Paris), volume 104, June 9, 1934, pages 511–15.

34. Combustion Control for Power Plants, **Gustaf A. Gaffert.** *Power Plant Engineering*, volume 38, July 1934, pages 314–15. Factors involved in the selection of the combustion control system to be employed and so forth.

35. Combustion-Control Systems, **J. L. Hodgson, L. L. Robinson.** Institution of Mechanical Engineers *Proceedings* (London), volume 126, 1934, pages 59–169; *Engineer* (London), volume 157, February 2, 1934, pages 132–4; abstract: Automatic Combustion Control for Boilers, *Engineering* (London), volume 137, February 2–9, 1934, pages 134–6, 162–4, abridgement. The development of automatic combustion control systems for industrial and power station boilers.

1935

36. Automatic Boiler Control in Steam Power Plants, **A. Heinig.** *Engineering Progress* (Berlin), volume 16, February 1935, pages 53–4.

37. Automatic-Combustion Control. Institute of Fuel *Journal* (London), volume 8, February 1935, pages 174–80; *Gas Journal* (London), volume 209, January 16, 1935, pages 143–4; abstract: Automatic Control for Gas and Coke-Fired Boilers.

38. Automatic Zoned-Air Control for Connors Creek Stokers. **Thomas Wilson.** *Power*, volume 79, March 1935, pages 128–9.

39. Combustion Control. *Power Plant Engineering*, volume 39, February 1935, pages 93–6, 106.

40. Large-Boiler Operation Goes Automatic, West Virginia Pulp and Paper Company, **E. H. Barry.** *Power*, volume 79, May 1935, pages 252–3.

1936

41. Automatic Control. *Power Plant Engineering*, volume 40, January 1936, pages 33–7.

42. Automatic Control of Electric Boilers on Fluctuating Loads, **M. Eaton.** *Electrical News and Engineering* (Toronto), volume 45, March 1, 1936, pages 20–3. "Maintains either constant adjustable pressure or constant adjustable power input as required."

43. Automatic Control of Steam Boilers (in French), **M. Wilfart.** *Memoires* Société des Ingénieurs Civils de France (Paris), volume 89, May, June 1936, pages 453–501; *Revue d'Electricité et de Mécanique* (Paris), May, June 1936, pages 26–36, July, August 1936, pages 28–44.

44. Combustion Control and Controllers, **Harvey C. Mittendorf.** *Combustion*, volume 7, March 1936, pages 20–6.

45. Combustion Control at Richmond Station, **N. J. Walker.** *Power*, volume 80, July 1936, pages 373–5.

46. Combustion Control for Oil Fired Boiler Plants, **Kalman Steiner, Paul R. Unger.** *Heating, Piping and Air Conditioning*, volume 8, October 1936, pages 544–7.

1937

47. Combustion Control. *Power*, volume 81, April 1937, pages 197–220.

48. Combustion Instruments and Control at Hell Gate, **Paul W. Keppler.** *Combustion*, volume 8, April 1937, pages 29–33.

1938

49. The Automatic Combustion Control at Fisk Station. *Electric Light and Power*, volume 16, October 1938, pages 41–3, 62. "On two 375,000-pound per hour pulverized-coal-fired 1200-pound boilers, combustion control equipped with a remote manual provision, excess-pressure pump and feedwater level control make operation automatic and aid in co-ordinating the high and low pressure systems."

50. Automatic Combustion-Control System, **H. Ziebolz.** *Instruments*, volume 11, October 1938, pages 228–54. A group of 28 short articles each describing a special system of combustion control.

51. Automatic Combustion Control at the Thorpe Power Station, Norwich. *Steam Engineer* (London), volume 7, May 1938, pages 324–9.

52. Combustion 1938 (a report of the combustion subcommittee of the prime movers committee, Edison Electric Institute publication number *F*12, November 1938). Includes some material on combustion control. Similar reports are available for other years.

53. Control Systems for Oil-Fired Boilers. *Heating, Piping and Air Conditioning*, volume 10, February 1938, pages 101–04. Recent practice in industrial installations described.

54. Automatic Control for Modern Boiler Plant. *Engineering and Boiler House Review* (London), volume 51, 1938, January, pages 440–2; February, pages 522–5; March, pages 594–7; April, pages 665–7; May, pages 741–4. Volume 52, 1938, June, pages 807–09; July, pages 34, 36, 38, 40; August, pages 79–83; September, pages 141–5; November, pages 289–91.

55. Thermal Supervisory Installation, for the Emergency Equipment of Simmering Power Plant, Vienna (in German), **Rudolf Mokesch.** *Zeitschrift des Vereines Deutscher Ingenieure* (Berlin), volume 82, April 9, 1938, pages 433–9. Illustrated description of automatic-control equipment for boilers and turbines.

1939

56. Automatic Boiler Control, Hagan System. *Engineer* (London), volume 168, December 22, 1939, pages 620–1.

57. Automatic Combustion Control at Hackney Borough Power Station. *Steam Engineer* (London), volume 8, May 1939, pages 326–9.

58. Automatic Combustion Control in Steam Power Plants (in French), **Robert Viatour.** *Revue Universelle Des Mines* (Liege), volume 15, July 1939, pages 361–74.

59. Best Efficiency at Lowest Cost Aim of Perry K Boiler Control, **T. W. Ayton.** *Electrical World*, volume 112, July 29, 1939, pages 286–8. Indianapolis Power and Light Company combines pneumatic and electric control.

60. Dual-Fuel-Fired Boilers Automatically Controlled, **A. L. Stewart.** *Power*, volume 83, October 1939, pages 605–07. "Combustion control on the high-pressure boilers, burning varying quantities of blast-furnace gas separately or in combination with pulverized coal, automatically adjusts fuel and air supply to maintain continuous practical-test conditions."

61. Savings at Sucrest, **Frank C. Staples.** *Power*, volume 83, April 1939, pages 196–7. "Automatic combustion control reduced coal consumption."

1940

62. Automatic Control Solves Dual-Fuel Problems, **W. E. Sachse.** *Power*, volume 84, August 1940, pages 492–4. "Difficult combustion and steam pressure problems caused by widely fluctuating gas supply and steam demands were solved by installing automatic combustion control on two boilers fired with oil-refinery gas and pulverized coal."

63. Combustion Systems, Controls for Gas-fired Boilers, **Henry Cooney.** *Oil and Gas Journal*, volume 39, August 22, 1940, pages 61–3, 66. Includes a discussion of some automatic control systems.

64. More Sensitive Control, **Reginald Trautschold.** *Steel*, volume 106, May 6, 1940, pages 74, 77. New automatic combustion control for chain grate, stoker-fired boilers is usually sensitive to load variations. It compensates for changes in heat value, and the moisture in the fuel.

65. Steam Power Stations (book), **Gustav A. Gaffert.** McGraw-Hill Book Company, Inc., New York, N. Y., 2d Edition, 1940, 592 pages; "Combustion-control systems," pages 331–9.

1941

66. Automatic Boiler Control, **J. E. O'Breen.** *Blast Furnace and Steel Plant*, volume 29, March 1941, pages 332, 334–5, 360.

67. Automatic Combustion Control Fires Four Fuels; Two Boilers Burn Coal, Pitch, Tar or Oil. *Power*, volume 85, January 1941, pages 25–7.

68. Automatic Electrically-Controlled Soot Blowers. *Engineering* (London), volume 151, June 20, 1941, pages 486–7.

69. Continuous Heat-Balance Control of Boiler-Room Operation, **Benjamin S. Murphy.** American Society of Mechanical Engineers *Transactions*, volume 63, November 1941, pages 669–75. Methods used at the Hudson Avenue Station of the Brooklyn Edison Company, Incorporated.

70. Instruments and Controls Increase Boiler Output, **Charles W. Parsons.** *Chemical Industries*, volume 48, May 1941, pages 610–14.

71. Steam-Pressure Regulation by Automatic Control, **E. S. Bristol.** *Power*, volume 85, April 1941, pages 242–4.

Automatic Hydroelectric Plants

1930

1. Automatic Hydroelectric Station in Australia, **H. D. Cook.** World Power Conference (Second) *Transactions* (Berlin), volume 13, 1930, pages 278–92.

2. Importance of Automatic Operation of Hydroelectric Plants for Power Production in Sweden (in German), **C. Kiessling.** World Power Conference *Transactions* (Berlin), volume 13, 1930, pages 248–77.

3. Recent Automatic Hydroelectric Power Stations, **W. L. Moore.** New Zealand Society of Civil Engineers *Proceedings* (Wellington), volume 17, 1930–31, pages 450–65.

1931

4. Automatic Central Stations Containing Several Turbine Sets As Well As Turbines With Several Distributors (in French), **F. Salgat.** *Schweizerische Bauzeitung* (Zurich), volume 97, April 25, 1931, pages 211–15. On automatic hydroelectric plants. Serial.

5. Automatic Control for Hydro Stations, **Frank J. Fink.** *Electric Light and Power*, volume 9, November 1931, pages 30, 32, 34, 36. "Some methods used in cutting from manual to automatic."

6. Automatic Generating Stations. *Electrical Canada* (Toronto), volume 8, January 1931, pages 10–13, 42.

7. Automatic Hydroelectric Generating Stations, **P. J. Croft.** *Electrical News and Engineering* (Toronto), volume 40, July 1, 1931, pages 36–9. Includes a table of data on Canadian installations.

8. Automatic Hydroelectric Plants (in German), **K. Piche.** *Elektrotechnik und Maschinenbau* (Vienna), volume 49, March 22, 1931, pages 213–23. Describes apparatus and methods for making hydro stations automatic.

9. Automatic Hydro-Plant Economy Proved by Experience, **J. M. Gaylord.** *Electrical World*, volume 97, March 21, 1931, pages 532–5.

10. Automatic Hydro Station at Rockton, Illinois, **E. J. Kallevang.** *Electric Light and Power*, volume 9, April 1931, pages 27–9. A new plant of the South Beloit Water Gas and Electric Company.

11. Automatically Controlled Power Station. *Electrical Review* (London), volume 109, July 24, 1931, page 130. Short description of a plant of the Power Corporation of Canada, Ltd., on the Montreal River.

12. Automatic and Remotely Controlled Hydropower Plant, **B. Fleck.** *AEG Progress* (Berlin), volume 7, May, June 1931, pages 99–106.

13. Bozingen Automatic Power Station of the United Wire Works, Ltd. (Bienne), **E. Soldati.** *Brown Boveri Review* (Baden), volume 18, December 1931, pages 371–3. Short description of an automatic hydroelectric plant in Switzerland.

14. Central Control for Large Hydro Plant (Saluda River Hydroelectric Station). *Electrical World*, volume 98, October 17, 1931, page 699.

15. Disk-Arm Pivot Valves Controlled Automatically, **J. Elmer Housley.** *Power*, volume 73, March 3, 1931, pages 368–9.

16. Electric Equipment of Saint-Sulpice Power Station of the Fabrique de Pates de Bois de la Doux, Serrieres (Switzerland), **E. Soldati.** *Brown Boveri Review* (Baden), volume 18, April 1931, pages 149–56. An automatic hydroelectric plant with Brown Boveri Electric Equipment.

17. 13,000-Horsepower Fully Automatic Hydroelectric Plant, **P. J. Croft, D. H. Hutchison, J. R. Desloover.** *Electrical News and Engineering* (Toronto), volume 40, March 15, 1931, pages 39–42, 48. The Upper Notch Plant of the Northern Ontario Power Company, near Cobalt, Ont.

18. Remote-Controlled Hydro Station. *Electrical World*, volume 98, July 25, 1931, page 154. Short account of the mode of operation of the General Control Corporation's remote-control apparatus for hydroelectric plants.

19. Thorenberg Electric Plant from 1885 to 1931 (in German), **H. Mueller.** Schweizerischer Elektrotechnischer Verein *Bulletin* (Zurich), volume 22, June 12, 1931, pages 288–95. Automatic operation.

20. The White Rapids Automatic Station of the Northern Electric Company, **H. W. Gochnauer.** *General Electric Review*, volume 34, September 1931, pages 507–11. An automatic hydroelectric plant in Wisconsin.

1932

21. Winter Construction of an Automatic Low-Head Hydroelectric Plant in Canada, **Robert Ferguson Legget.** Institution of Civil Engineers (London), number 117, 1931.

22. Automatically Controlled Central Hydro Plant of Fioritella (in Italian), **S. Ruberti.** *L'Energia Elettrica* (Milan), volume 9, October 1932, pages 889–93.

23. Automatic Control of Water Level and Discharge in Power Canals (in Japanese), **S. Kambara.** Civil Engineering Society, Japan, *Journal* (Tokyo), July 1932, pages 705–62. Principles of design of automatic flow control systems.

24. Automatic Hydro Plants, **B. Fleck.** *Engineering Progress* (Berlin), volume 13, September 1932, pages 205–08.

25. Automatic Power Plant Serves Wyoming Ranches, **Hammond Mathews.** *Electric Journal*, volume 29, May 1932, pages 248–9.

26. Equipment of Tukimosi Automatic Power Station (in Japanese), **T. Saburo.** *Shibaura Review* (Tokyo), May 1932, pages 165–78.

27. Hirotaki Outdoor Automatic Power Plant Number 2 (in Japanese), **K. Gizyutubu, K. Rinpei.** *Shibaura Review* (Tokyo), August 1932, pages 303–14.

28. Plant Rehabilitation Improves Operations, **J. B. Davenport, E. M. Scott.** *Electrical World*, volume 100, December 31, 1932, pages 876–9. Borel hydro plant of the Southern California Edison Company rebuilt for automatic operation.

29. Remote Control Equipment of Oberhasli Hydroelectric Plant (in German), **K. Keller.** *Siemens Zeitschrift* (Berlin), volume 12, March 1932, pages 85–9.

1933

30. Automatic Control Equipments at Shimotaki and Nakaiwa Power Stations of Kinugawa Hydroelectric Power Company (in Japanese), **S. Miki.** Institute of Electrical Engineers, Japan, *Journal* (Tokyo), volume 53, December 1933, pages 1070–1.

31. Automatic Devices of the Calusia Hydroelectric Plant (in Italian), **M. Covino, M. Melogli.** *L'Elettrotecnica* (Milan), volume 20, May 25, 1933, pages 334–44; June 5, 1933, pages 357–70; August 5, 1933, pages 514–16.

32. Automatic Hydroelectric Plants, **F. Johnstone Taylor.** *Electrical Review* (London), volume 112, April 21, 1933, pages 557–8.

33. Automatic Hydroelectric Plant at the Third Falls of the Neto River, Italy (in Italian), **M. Mortara.** *L'Electrotecnica* (Milan), volume 20, March 15, 1933, pages 161–7.

34. New Control for Automatic Water Power Installation, **A. Gagg.** *Escher Wyss News* (Zurich), volume 6, May, June 1933, pages 85–7.

35. Photo-Cell Control Executes Predetermined Hydro Operation, **John Fies.** *Electrical World*, volume 102, September 23, 1933, pages 396–8.

36. Semiautomatic Operation Obtained at Low Cost, **L. M. Robertson.** *Electrical World*, volume 102, October 7, 1933, page 468–9. Public Service Company of Colorado, Summit and Fall River hydro plants.

37. Supervisory Control and Automatic Protection in Hydroelectric Developments, **Howard Fellows.** *Mechanical Engineering*, volume 55, December 1933, pages 767–8; *Engineering Journal* (Montreal), volume 16, October 1933, pages 417–22.

1934

38. Automatic Control and Remote Control in the Operation of Hydroelectric Plants (in German), **Felix Jager.** *Siemens Zeitschrift* (Berlin), volume 14, July 1934, pages 229–34; (in English). *Siemens Review* (Berlin), volume 11, number 1, 1935, pages 8–13.

39. Automatic Hydroelectric Power Plant at Reno Gold Mines British Columbia, **F. C. Barnes.** *Canadian Mining Journal* (Quebec), volume 55, June 1934, page 278; *Electrical News and Engineering* (Toronto), volume 43, April 15, 1934, page 37.

40. Automatic Remote Control of the "Steirischen Wasserkraft, und Elektrizitats A.-G. Steweag" (in German), **Hans Eigl.** *Elektrotechnik und Maschinenbau* (Vienna), volume 52, March 11, 1934, pages 109–14.

41. Controlling Kaplan Unit Having Dual Service, **John Fies.** *Electrical World*, volume 103, January 20, 1934, pages 104–05.

42. Economies from Automatic Operation; Poole Plant, Southern Sierras Power Company System, **Frank A. Ayres.** *Electrical West*, volume 72, January 1934, pages 19, 21.

43. Hydroelectric Project at Lochaber. *Canadian Engineer* (Toronto), volume 67, August 28, 1934, pages 10–11.

44. The Malga Mare Automatic Hydroelectric Plant (in Italian), **Emilio Santuari.** *L'Energia Elettrica* (Milan), volume 11, July 1934, pages 536–58. Methods of power regulation and operation of plant.

45. A New Automatic Power Station Designed for Remote Control, **H. Ahlen.** *ASEA Journal* (Västeras), volume 11, November, 1934, pages 154–60. Illustrated account of Allmanna Svenska Elektriska Aktiebolaget equipment in a small hydroelectric plant in Sweden.

46. New Remote-Controlled Automatic Hydroelectric Plant (in Swedish), **H. Ahlen.** *ASEA'S Tidning* (Västeras), volume 26, August 1934, pages 114–19. Illustrated description of a Swedish installation of Asea manufacture.

47. Unattended Hydraulic Power Stations. *Bulletin Oerlikon* (Oerlikon; Zurich), March–April 1934, pages 845–50. An illustrated description of Oerlikon apparatus for such stations.

48. Aatorp Unattended Hydroelectric Power Station, **Konrad Schinkler, Felix Jager.** *Siemens Review* (Berlin), volume 11, November 1, 1935, pages 13–22; (in German) *Siemens Zeitschrift* (Berlin), volume 14, July 1934, pages 234–44. General illustrated description of plant and equipment.

1935

49. Automatic Hydroelectric Plants (in German), **K. Piche.** *Elektrotechnik und Maschinenbau* (Vienna), volume 53, April 14–21, 1935, pages 169–74, 185–8. An explanation of the construction and functioning of fully automatic plants, together with detailed description of two such plants now in operation.

50. Automatic Hydroelectric Plant for Restaurant and House. *Electrical Review* (London), volume 116, January 4, 1935, page 13.

51. "Colli al Volturno" Automatic Hydroelectric Plant (in Italian), **G. D. Cangia.** *L'Elettrotecnica* (Milan), volume 22, August 10, 1935, pages 538–46. Illustrated description of an Italian plant of subsidiary nature operating in parallel with a main plant.

52. Plant Controlled Over 23-Mile Line. *Electrical World*, volume 105, November 9, 1935, page 2696. Canaan hydro-electric plant of the Public Service Company of New Hampshire.

53. Remote Control of Laholm Power Station, **C. Kiessling.** *ASEA Journal* (Vasteras), volume 12, January 1935, pages 62–5; (in Swedish). *ASEA'S Tidning* (Västeras), volume 27, January 1935, pages 2–5. A Swedish automatic hydroelectric plant.

1936

54. Automatic Hydro Control, **T. B. Montgomery.** *Allis-Chalmers Electrical Review*, volume 1, December 1936, pages 23–5. An example of its adaptability to specific requirements.

55. Equipment of Automatic Hydroelectric Central Stations (in Italian), **C. Cardini.** *L'Elettrotecnica* (Milan), volume 23, November 23, 1936, pages 682–91; December 10, 1936, pages 722–34.

56. Farfa Second Falls Automatic Hydroelectric Plant (in Italian), **G. R. Panbianco.** *L'Elettrotecnica* (Milan), volume 23, December 25, 1936, pages 750–9.

57. Foolproof Hydro Plant. *Electrical World*, volume 106, April 25, 1936, pages 1176–7. The Twin Falls automatic hydroelectric plant of the Idaho Power Company.

58. La Chatre and Chauvan Automatic Hydroelectric Plants of the Société des Forces Motrices de la Vienne (in French), **Lucien Besnard, Rene Langlois.** *Revue Générale de l'Electricité* (Paris), volume 40, October 17–24, 1936, pages 503–17, 535–51.

59. Nonattended Three-Phase Water Power Stations, **B. Fleck.** *AEG Progress* (Berlin), November 4, 1936, pages 77–80.

1937

60. Automatic Equipment for Hydroelectric Plants (in French), **L. Armanet, M. Mayer.** *Revue d'Electricité et de Méchanique*

(Paris), May, June 1937, pages 1–12; July, August 1937, pages 1–11.

61. Automatic Hydro Plant. *Power Plant Engineering*, volume 41, March 1937, pages 177–9. A municipal plant at Lansing, Mich.

62. Automatic Innovations Feature Diablo Hydro Plant, **Richard F. Stevens.** *Electrical World*, volume 108, August 14, 1937, pages 63–6, 132–3. One-floor power house layout; unit assembly of generators and transmission lines; automatic printed log of operations; automatic load and frequency control; wiring diagrams of system given.

63. Design Features of the London and Marmet Hydro Developments, **Philip Sporn, E. L. Peterson.** *Power Plant Engineering*, volume 41, February 1937, pages 80–7. Two low-head automatic hydro plants located on the Kanawha River, near Charleston, W. Va.

64. Electrical Equipment at Automatic Hydroelectric Stations in the USA (in Russian), **M. P. Suslov.** *Elektrichestvo* (Moscow), volume 1, January 1937, pages 23–8.

65. Fully Automatic Hydroelectric Plant With Remote Control by Means of Carrier Current (in Swedish), **Yngve Hedin, Holger Ahlen.** *ASEA'S Tidning* (Västeras), volume 29, November 1937, pages 162–9. An installation in Sweden.

1938

Simplified Calculation of Fault Currents

A simplified procedure for the calculation of short-circuit currents was presented in an earlier report.[1] This procedure, outlined in this article, has been given trial use for over a year and has been found to be generally satisfactory for the purpose intended. Accordingly, it is now recommended for general use by the industry as a simplified method of approximating the magnitude of fault currents.

THE precise determination of short-circuit currents involves a calculation so laborious as to be generally impractical. Thus, some approximation is required, and a degree of judgment must be applied in any method proposed. This method presented here is based upon the determination of an initial value of rms symmetrical current with which multiplying factors are used for application purposes. It is proposed that it be used, where applicable, in place of the methods which involve the use of decrement curves. It is believed that this procedure is sufficiently accurate to serve as a reliable basis for the application of interrupting devices and for a preliminary basis for relay settings.

The recommended multiplying factors take account of generator decrement and the asymmetrical value of current as influenced by the system d-c time constant, and they are adjusted to make allowance for the increase in generator excitation required to maintain normal terminal voltage under load conditions. They neglect, however, such influences as generator voltage regulators and phase-angle differences between generator rotors, which have but little effect within the usual operating time of modern circuit breakers.

A comparison of the current magnitudes determined by the recommended factors with those calculated by more complicated methods after various time intervals is given in Figure 1. The time intervals selected correspond to breaker speeds of 2, 3, 5, and 8 cycles. The fault current and reactances are based on the system kilovolt-amperes. Curves are given for both the total rms current and the a-c component only, the difference between the two being due to the d-c component. The larger the d-c time constant, the more closely is the total rms curve approached, and the smaller the d-c time constant, the more closely is the a-c component curve approached. The time constant of the d-c component for which these curves were made is 0.15 second or nine cycles, which is larger than the values usually encountered in any equipment except generators. The d-c time constant may be expressed generally as equal to $(1/2\pi f)(X/R)$ in seconds, or $(1/2\pi)(X/R)$ in cycles, where X is the 60-cycle reactance and R the d-c resistance to the point of fault.

This report, sponsored by the AIEE committee on protective devices (J. R. North, chairman 1940–42) was prepared by a working group consisting of W. F. Skeats, W. M. Hanna, J. B. MacNeill, H. A. Travers, C. F. Wagner, and C. A. Woodrow.

This report is reprinted from *Electrical Engineering,* volume 61, October 1942, pages 509–11.

In this method of determining fault currents, symbols are used with the following significance:

E = leg voltage
X_1 = direct-axis reactance, either transient or subtransient as specified, in ohms per leg
X_2 = negative-sequence reactance
X_0 = zero-sequence reactance
R_0 = zero-sequence resistance

The type of fault (number of phases involved, with or without ground) which will result in the maximum fault current varies with the relative values of the different circuit constants.

The three-phase short-circuit current is E/X_1. The line-to-line short-circuit current is $\sqrt{3}E/(X_1+X_2)$. Since X_2 is usually equal to or greater than X_1, this current seldom exceeds 86 per cent of the three-phase short-circuit current, and, consequently, for line-to-line faults the three-phase fault-current value is generally satisfactory.

The line-to-ground short-circuit current is $3E/(X_1+X_2+X_0)$. Since X_2 is usually approximately equal to X_1 (using the subtransient value for X_1), this expression is often shortened to $3E/(2X_1+X_0)$. In practical cases, regardless of the value X_2, this last expression is satisfactory for determining the current in a double line-to-ground fault.

PROCEDURE

The following gives a résumé of the procedure and the various multiplying factors to be used with currents calculated by the formulas just stated. Tables I and II show what reactance quantity should be used for representing the machines in the positive-sequence network.

Circuit Breakers, Protector Tubes, and Fuses. Determine "highest value of rms symmetrical current for any type of fault" by E/X_1 or $3E/(2X_1+X_0)$, whichever is greater, except that when R_0 is greater than $5X_1$, no consideration need be given to the latter term. Use multiplying factors as given in Table I for specific type of apparatus.

The application of protector tubes requires also the calculation of minimum fault current with minimum connected synchronous capacity and symmetrical current using E/X_1 or $3E/(2X_1+X_0)$, whichever gives the lower value. Special consideration is required where tower-footing resistance can appreciably reduce this line-to-ground fault current. For further details reference may be made to a paper, "Protector Tubes for Power Systems."[2]

Fuses are rated on total current, and, as the time durations involved are very short, their required inter-

rupting capacity should be based on the total rms current at one-half cycle. Two cases should be considered:

1. In the general case, the current multiplying factor is 1.6, using subtransient reactance for all machines, and including both synchronous- and induction-motor contributions.

2. For fuses rated 15,000 volts or below with interrupting ratings not exceeding 3,000 amperes (except when applied on a generator bus), the resistance introduced by line and transformer is so great that the rms current of a maximum displaced wave in the first half cycle will not exceed 1.2 times the calculated symmetrical current, using subtransient reactance. Application on this basis may be considered safe.

Mechanical and Momentary Ratings. For many purposes, it is necessary to know the maximum possible rms current which can flow in the circuit. This is the current, including both a-c and d-c components, as calculated at one-half cycle. Allowing for over excitation of generators on account of load, the rms value of current as calculated for zero time is about 1.8 times the value calculated by dividing leg voltage by subtransient reactance. As there will always be some decay even in the first half cycle, however, a multiplier of 1.6 gives a safe figure.

In some instances, as when transmission line or cable reactance is an important factor in the limitation of current, the factor 1.6 may be higher than necessary. In such applications at 5,000 volts and below, the ratio of reactance to resistance is sufficiently low so that the d-c component decreases very greatly during the first half cycle. Thus within this voltage range, and except where the bulk of the power is supplied by generators at the point of fault, a standard factor of 1.4 may be used instead of 1.6. A standard factor is particularly desirable, in consideration of the difficulties of obtaining actual resistance figures and the distribution of the d-c component among contributing short-circuit sources.

Low-Voltage Systems. Low-voltage air circuit breakers (rated 600 volts or less) are often instantaneous in operation and part contacts during the first half cycle. These breakers, however, are rated on the basis of average current in the three phases, and circuits on which they are installed rarely have X/R ratios exceeding 10. This corresponds to an average rms current during the first cycle equal to 1.23 times the symmetrical current. Such breakers may therefore be applied on the basis of 1.25 times the three-phase initial symmetrical current using subtransient reactance and including both synchronous and induction motors.

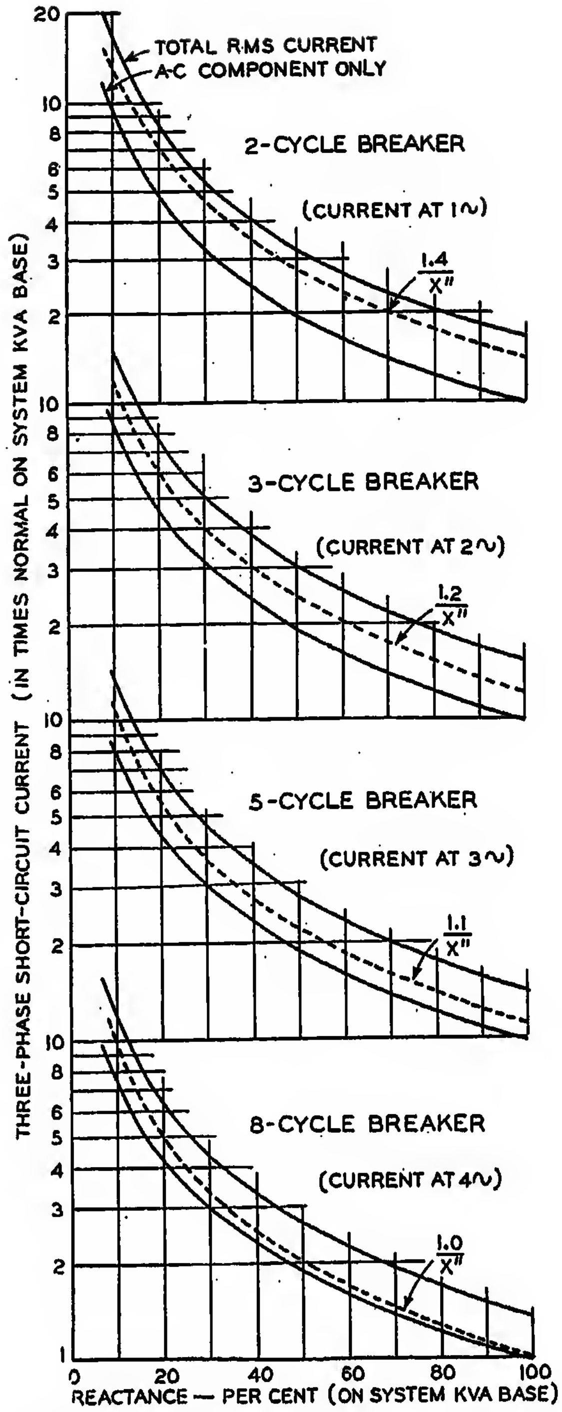

Figure 1. Comparison between decrement curve calculations and calculations by the proposed method

Table I. Circuit Breakers, Protector Tubes, and Fuses

	Multiplying Factor	Reactance Quantity for Use in X_1: Synchronous Generator	Synchronous Motor	Induction Machine
A. Circuit-Breaker Interrupting Capacity				
1. General case				
Eight-cycle or slower breakers ∮	1.0	Subtransient*	Transient	
Five-cycle breaker	1.1	Subtransient*	Transient	
Three-cycle breaker	1.2	Subtransient*	Transient	
Two-cycle breaker	1.4	Subtransient*	Transient	
2. Short circuits fed predominantly by large machines at the point of fault may be increased up to 20 per cent				
3. Air circuit breakers rated 600 volts and less	1.25	Subtransient	Subtransient	Subtransient
B. Mechanical Stresses and Momentary Rating of Circuit Breakers				
1. General case	1.6	Subtransient	Subtransient	Subtransient
2. At 5,000 volts and below, unless current is fed predominantly by directly connected synchronous machines or through reactors	1.4	Subtransient	Subtransient	Subtransient
C. Protector Tubes				
1. Maximum rating	1.0	Subtransient	Subtransient	Subtransient
2. Minimum rating—use minimum system capacity and minimum of E/X_1 or $3E/(2X_1+X_0)$	1.0	Subtransient	Subtransient	Subtransient
D. Fuses				
1. General case	1.6	Subtransient	Subtransient	Subtransient
2. At 15,000 volts or below with interrupting ratings not exceeding 3,000 amperes	1.2	Subtransient	Subtransient	Subtransient

∮ Modern breakers are likely to be more effective than their slower predecessors, and, therefore, the application procedure with the older breakers should be more conservative than with modern breakers. Consequently, the factors to be used with older and slower breakers should be the same as for modern eight-cycle breakers.

* This is based on the condition that any hydroelectric generators involved have amortisseur windings. For hydroelectric generators without amortisseur windings, the subtransient reactance should be assumed equal to 75 per cent of the transient reactance for this calculation.

Table II. Preliminary Settings for Relays

	Multiplying Factor	Reactance Quantity for Use in X_1: Synchronous Generator	Synchronous Motor	Induction Machine
1. High-speed current actuated	1.0	Subtransient	Subtransient	Subtransient
2. Time overcurrent	1.0	Transient	Transient	

In calculating the equivalent system impedances, it should be remembered that at low voltages even small impedance values become of importance, and all elements of the circuit, including current transformers, disconnects, switches, bus runs, and lead wires, should be taken into consideration.

Overcurrent Protective Relays. In approximating the settings of overcurrent relays, the fault currents for two conditions should be determined:

1. The maximum initial symmetrical current for maximum connected synchronous capacity as determined by E/X_1 or $3E/(2X_1+X_0)$, whichever is greater, except that, when R_0 is greater than $5X_1$, no consideration need be given to the latter term.

2. The minimum symmetrical current for minimum connected synchronous capacity as determined by $0.866E/X_1$. In particular situations allowance should be made for remote fault locations and fault resistance.

Ground, distance, balanced, and other types of relays require special consideration.

Report of the Board of Directors

THE BOARD OF DIRECTORS of the American Institute of Electrical Engineers presents herewith to the membership its 58th annual report, for the fiscal year ending April 30, 1942. A general balance sheet showing the condition of the Institute's finances on April 30, 1942, together with other detailed financial statements, is included herein. This report contains a brief summary of the principal activities of the Institute during the year, more detailed information having been published from month to month in *Electrical Engineering.*

BOARD OF DIRECTORS' MEETINGS

The board of directors held five meetings during the year, four in New York, N. Y., and one in Toronto, Ont.

Information regarding many of the more important activities of the Institute which have been under consideration by the board of directors and the committees is published each month in the section of *Electrical Engineering* devoted to Institute activities.

DEFENSE AND WAR ACTIVITIES

In accordance with a resolution adopted by the board of directors on June 27, 1940, offering the services of the Institute to the President of the United States in connection with national defense problems, the board, committees, Sections, and headquarters staff have co-operated fully at every opportunity.

In addition to the organization of a committee on national defense, and a committee on civil protection, the Institute appointed a representative on the National Technological Civil Protection Committee and five representatives on the Engineers' Defense Board.

Co-operation has been extended in many undertakings, including the National Roster of Scientific and Specialized Personnel, census of engineering construction firms, extension of subcontracting plans, study of supply of and demand for engineers, and others.

President D. C. Prince delivered his address on the subject of postwar planning at meetings of many Sections and other organizations, and it was received with keen interest.

Editor G. Ross Henninger has contributed a substantial amount of his time weekly, since January 23, 1942, to the United States Navy Department, in Washington, in the organization of an editorial and publication review section for the co-ordination of Navy technical material.

Assistant Editor W. R. MacDonald, Jr., as a first lieutenant in the United States Army Signal Corps Reserve, was called into active service in January 1941 and has since been promoted to the rank of captain. He is responsible for the preparation and distribution of technical material used throughout the Signal Corps.

PRESIDENT'S AND NATIONAL SECRETARY'S VISITS

President Prince and National Secretary H. H. Henline attended the summer and Pacific Coast conventions, winter convention, South West District meeting in St. Louis, Mo., Southern District meeting in New Orleans, La., and the North Eastern District meeting in Schenectady, N. Y. President Prince and National Secretary Henline will attend the summer convention in Chicago, Ill. In May, the president will visit the Cleveland Section, and the national secretary will visit the Rochester Section.

ANNUAL MEETING

The annual business meeting of the Institute was held on Tuesday morning, June 17, 1941. The annual report of the board of directors for the fiscal year which ended April 30, 1941, was presented in abstract by the national secretary. A report on the finances of the Institute was presented by National Treasurer W. I. Slichter. The report of the committee of tellers upon the election of officers for the year beginning August 1, 1941, was presented, and President-Elect Prince responded to his introduction with a brief address. During this session, there was an address by Doctor Thomas H. Hogg, chairman and chief

engineer of the Hydro-Electric Power Commission of Ontario, and the Lamme Medal for 1940 was presented to Doctor Comfort A. Adams, consulting engineer, Edward G. Budd Manufacturing Company, Philadelphia, Pa.

NATIONAL CONVENTIONS

Three national conventions were held during the year, and a brief report on each follows:

Summer Convention. The 57th summer convention was held in Toronto, Ont., June 16–20, 1941. In addition to the annual business meeting, and conference of officers, delegates, and members, there were ten technical sessions, five technical conferences, and one general session, at which Howard Coonley, of the Walworth Company, gave an address entitled "Making Democracy Work." Entertainment features of the convention were an English tea, bridge, dance, banquet, and golf and tennis tournaments. Many inspection trips were held. The registration was 1,203.

Pacific Coast Convention. The 29th Pacific Coast convention was held in Yellowstone National Park, August 27–29, 1941, with a registration of 322. A conference on "After the Emergency, What?" was a feature of the program, which also included three technical sessions, two technical conferences, one general session, two student sessions, and a conference on student activities. Entertainment features included an informal dinner and dancing, boat trip, inspection trips, and ladies' events.

Winter Convention. The 30th winter convention was held in New York, N. Y., anuary 26–30, 1942, with a program including 20 technical sessions, at which more than 70 papers were presented, and 6 technical conferences. At the general session, N. G. Symonds, consultant on co-ordination of conservation orders, War Production Board, gave an address entitled "The Engineer's Contribution to the War Effort," and the Alfred Noble Prize was presented to Robert F. Hays, Jr. At an evening meeting, the Edison Medal was presented to Doctor John B. Whitehead, professor of electrical engineering, The Johns Hopkins University, Baltimore, Md. A smoker, dinner dance, and events for women guests completed the program. The registration was 1,331.

DISTRICT MEETINGS

South West District Meeting. This meeting was held in St. Louis, Mo., October 8–10, 1941, with 530 members and guests attending. Seven technical sessions, one general session, and two technical conferences were held. An address by E. T. Gushee, executive vice-president, Union Electric Company of Missouri, on "Electric Utilities' Part in National Defense" was given at the general session, and postwar problems were discussed at a general luncheon at which Doctor William McClellan, president, Union Electric Company, presided, and President Prince gave his address on postwar planning. Entertainment features consisted of a smoker, banquet and dance, women's bridge, and many inspection trips.

Southern District Meeting. The fourth meeting of this District was held in New Orleans, La., December 3–5, 1941. One general session, two technical sessions, and two student sessions were held at which eight papers were presented, in addition to the annual District conference on student activities. Entertainment consisted of a banquet, dancing, golf, and many inspection trips. The attendance was 384.

North Eastern District Meeting. This meeting, held in Schenectady, N. Y., April 29–May 1, 1942, was of wide interest on account of the quality and diversity of the program. There were one general session, three technical sessions, seven conferences, one student session, a joint luncheon with the Schenectady section of The American Society of Mechanical Engineers, a conference on student activities, a banquet, the Steinmetz memorial lecture, inspection trips, and other features. Attendance was about 500.

SECTIONS

During the year, the Sections committee recommended to Section chairmen that (*a*) plant engineers groups be formed, especially in the industrial centers, (*b*) efforts be made by the Sections to reinterest executives no longer engaged in technical work, (*c*) consideration be given to the desirability of organizing local engineering councils, and having some Section meetings devoted to civic affairs or related nontechnical subjects, (*d*) the Sections send announcements of their meetings to their members serving in the armed forces, (*e*) the Sections encourage their members to take keen interest in the development of plans for return to peacetime conditions, and (*f*) the interest in student guidance work in the Sections be increased.

President Prince gave his address on postwar planning at meetings of many of the Sections, and the keen interest with which it was received produced extensive discussions.

At its January meeting the board of directors voted to assign to Sections all remaining unassigned territory within the United States.

A majority of the Sections included in their programs during the year various phases of war activities.

Table I contains information regarding Sections and Branches and their meetings during the past several years. Detailed information on their activities of the past year may be found in the annual report on Section and Branch activities in the June 1942 issue of *Electrical Engineering*, pages 322–3.

STUDENT BRANCHES

A new Branch was organized at the University of Delaware, bringing the total number to 124.

The committee on Student Branches transmitted to all counselors pamphlet copies of Doctor William E. Wickenden's address "The Second Mile" (*Electrical Engineering*, May 1942, pages 242–7), suggesting that it be brought to the attention of students as an excellent statement of the nature of the engineering profession.

The committee on safety again urged the Branches to hold meetings on safety subjects, and transmitted detailed suggestions regarding such meetings.

The terms of 1,761 enrolled students were expected to expire on April 30, 1942. Of these, 935, or about 53 per cent, applied for admission as Associates.

See references at end of the preceding report on Sections.

General Committees

FINANCE COMMITTEE

In recommending a budget for the current appropriation year beginning October 1, 1941, the finance committee estimated that, in spite of the further loss of overseas revenue and loss from members in the United States enrolled in military service, the income for the current year would be approximately the same as that received during the previous appropriation year ending September 30, 1941, these losses being offset by the continued net increase in the membership of the Institute. So far, this expectation appears to be justified.

Accordingly, the budget was set up on the basis of $337,000, approximately $20,000 more than was expended last year. This has made possible a modest increase in the scope of the Institute activities in many departments including the publication of more technical material, some increases in salary to junior members of the staff and the addition of two people, a more liberal provision for the pension fund, and some increase in provision for travel, particularly for District student conferences. While the budget provides for some increases in expenses in

Table I. Section and Branch Statistics

	For Fiscal Year Ending April 30					
	1937	1938	1939	1940	1941	1942
Sections						
Number of Sections	62	65	67	70	72	72
Number of meetings held	621	624	635	701	703	647
Total attendance	74,950	110,148	85,692	91,949	92,554	78,254
Branches						
Number of Branches	119	120	120	121	123	124
Number of meetings held	1,363	1,334	1,190	1,346	1,163	946
Total attendance	46,121	60,446	53,380	64,972	52,285	37,785

addition to salaries, the budget includes an item of unappropriated funds of about $7,000, which it is anticipated should provide for additional necessary items and also for such further increase in the cost of materials as may take place during the year.

In taking care of the Institute's investment funds, the conservative policy of last year has been continued. About 20 per cent of the funds are invested in common stocks of essential industries and the bulk of the remainder is invested in United States Government bonds. Details of the Institute's investments are shown in Schedule 1 on page 379.

The Institute's healthy financial condition is the result of the policy continued over many years of budgeting expenses on the basis of the anticipated revenue and keeping the expenses within this budget limit. To the accomplishment of this, all parts of the Institute organization, and particularly the staff, have contributed. As a result, there has been built up over the life of the Institute a reserve fund of about $250,000, or about three-fourths of a year's expenses at the current level. In these disturbed times, it is very reassuring to have this modest insurance against any sudden great change in the Institute's income or expenses that might result from the war.

TECHNICAL PROGRAM COMMITTEE

Convention Programs. Three national conventions and three District meetings were held during the year. The total attendance of these six meetings represents a 1.5 per cent decrease as compared with the total attendance of five meetings held during the previous year. The attendance for the present year was unusually good when it is considered that the attendance at three of the meetings of the previous year each established a record over corresponding meetings in respective localities. When compared with the year ending April 30, 1939, in which six meetings were held, the attendance for the past fiscal year represents a 4.0 per cent increase. The 73 technical sessions and conferences at the six meetings were sponsored by 15 different Institute committees. Five of the technical committees held no sessions during the year.

The committee has arranged programs to be of the greatest service to the nation's war effort, in so far as possible. Five sessions and conferences of immediate importance to the war effort were held during the winter convention. These sessions were among the best attended, and in the planning of future programs sessions directly related to problems arising from the war will take precedence.

Civic Affairs Conferences. Several conferences on civic affairs have been held during the year to survey and determine how engineers can render the most effective service in their communities during the war and in the postwar period. In a conference on "After the Emergency, What?" held during the Pacific Coast convention, President Prince presented a plan based on studies made in the General Electric Company with a view to maintaining a high level of production during the peace to follow, and to prevent unemployment. Similar studies of business in various communities, states, and throughout the United States have been encouraged through discussions at subsequent conventions and Section meetings. A conference on "How Can Engineers Render Greater Public Service?" was held during the South West District meeting in St. Louis, Mo. Reports were submitted by 14 local engineering groups or councils on "The Contributions of Local Engineering Councils to Their Communities." Another such conference was held during the winter convention, in which a report of the St. Louis conference was presented by F. A. Cowan, vice-chairman of the technical program committee. "Regional Planning in the State of Pennsylvania" was described by R. H. Smith, deputy secretary, department of commerce, Commonwealth of Pennsylvania. Detailed reports of these two conferences on civic affairs were published in *Electrical Engineering*, March 1942, pages 148–52. Arrangements have been made to hold a similar conference on local engineering councils during the summer convention in Chicago.

Table II. Technical Programs, Last Four Years

	Year Ending April 30			
	1942	1941	1940	1939
Number of national conventions	3	3	2	3
Number of District meetings	3	2	3	3
Registration at national conventions and District meetings	4,274	4,339	3,548	4,100
Number of papers presented	182	195	177	184
Number of papers recommended for *Transactions*	152	167	151	169
Estimated number of pages required for printing papers in *Transactions*	807*	938*	886*	986*
Average length of papers recommended for *Transactions*	5.3	5.72	5.86	5.83
Number of technical sessions	50	46	43	50
Number of technical conferences	23	18	10	12

* Partly estimated.

Restricted Sessions. When subjects on which secrecy is required are discussed, closed committee meetings are held. During the winter convention, a session and conference on air transportation were successfully held with the attendance limited to AIEE members who are United States citizens and a few other strictly accredited individuals.

Conferences. During the war period, especially, technical conferences with a minimum of time-consuming formalities are encouraged. The accompanying tabulation shows that a greater number of conferences has been held during the past year than ever before, bringing their total number to 95 since their origin at the summer convention at Ithaca, N. Y., in 1935. The smaller number of technical papers presented, together with the maintained attendance at conventions, reflect the increasing importance of the conference method in providing up-to-the-minute reports of new developments, and free discussion of controversial questions.

General Sessions. A general session was held at each meeting during the year. Preference has been continued for addresses dealing with the broader problems of the profession, as related to co-operative effort during and after the war period, rather than toward specific technical developments. The general session of the 1942 summer convention will present some of the problems of engineering executives for the consideration of Institute members, through a discussion of "Organization and Management of Large-Scale Engineering Work."

Acknowledgments. The committee gratefully acknowledges the interest and efforts of its members and the work of the chairmen of the technical committees and the members of the headquarters staff.

PUBLICATION COMMITTEE

Electrical Engineering, *Transactions*, and advance pamphlet copies of technical program papers were published during the fiscal year in general on the same basis as for the preceding year.

The program and policy for expediting the publication of AIEE *Transactions* material that was initiated at the summer convention in Swampscott, Mass., in 1940, involved among others three related objectives.

The primary among these objectives was the earlier publication of *Transactions* material. This objective was achieved, effective with the January 1942 issue of *Electrical Engineering*. The first of the 1942 winter convention papers were published in the *Transactions* section of that issue, and the publication of the entire program of winter convention *Transactions* material will be completed with the June 1942 issue of *Electrical Engineering* and the corresponding June "Supplement to *Electrical Engineering—Transactions* Section." This latter supplement will, in contrast to the several previous issues, be down to what is considered normal size—200 pages or less. Also normal with respect to content, it will carry all the published discussions of 1942 winter convention papers but only a very few of the papers themselves—those which for some special reason could not be accommodated in the *Transactions* sections of the previous monthly issues of *Electrical Engineering*.

Requirements of the first objective imposed a second—that the publication of all 1941 papers and discussions and those remaining from 1940 be completed with the 1941 *Transactions* and the corresponding issues of *Electrical Engineering*.

This objective was achieved as originally scheduled, although as expected the program resulted in great enlargement of the June and December 1941 "Supplements" and imposed a delay of several weeks in the

completion and distribution of the 1941 *Transactions* volume. These latter manifestations were incidental to the transition in publication procedure, and should not be encountered in the ensuing normal application of the Swampscott program.

A third objective of the Swampscott program was that each annual volume of AIEE *Transactions* should contain all, *and only*, the technical program papers and related discussions presented during the corresponding calendar year and other appropriate record material for that year. The 1942 volume is expected to meet this objective.

The achievement of these desired results imposed many added burdens on the headquarters staff and introduced many transient difficulties into the work of the several committees responsible for the development of technical program material. The publication committee is duly appreciative of the effective co-operation of all parties involved.

World war conditions as of May 1, 1942, have introduced certain problems in the conduct of the Institute's publication service that seem worthy of recording. One of these relates to the matter of censorship-export control of the distribution of the monthly issues of *Electrical Engineering* to members and nonmember subscribers in all foreign countries and territories except Canada. Distribution has been entirely stopped in Asia to Burma, Japan, Netherlands Indies, Philippine and other islands, occupied portions of China, Malayan states, Indo-China, and other enemy-dominated territory; in Europe to all points except Great Britain, Turkey-in-Europe, and Russia. This affects about 230 members and 34 subscribers. Distribution to members and subscribers in Central and South America and the other remaining world points now is being made under export-license control and rigorous limitations imposed by the United States Office of Censorship and the Office of Export Control of the Board of Economic Warfare. Currently this affects about 720 Institute members and 205 subscribers.

MEMBERSHIP COMMITTEE

Membership of the Institute at the end of the fiscal year reached an all-time high record for that date of 18,944 exceeding the former peak year of 1927 by 600 members. This very creditable showing was undoubtedly the result of the hard work and unselfish efforts of the members of the Section membership committees, Branch counselors and members of the national membership committee, comprising approximately 700 Institute members engaged in membership work. This result was made possible to a considerable extent by the splendid response of the members of the Institute at large to the broadcast letter of the chairman, dated October 8, 1941, in which they sent in the names of 989 prospects, many of whom are now members. With the pressure of the war effort and unexpected demands upon the time of membership committee personnel, the amount of effort applied to Institute membership work is another indication of the fine spirit of loyalty which binds members of the Institute together in a national organization of their profession.

Table III shows that the gross increase in membership during the year was 1,863 and that this was reduced to a net increase of 1,058 by membership losses during the year. In the preceding year the gross increase was 1,644, reduced to a net increase of 673 by losses during that year. Analysis of the losses as between these two years is of interest in manifesting effective effort of membership committees in connection with delinquent members.

	Year Ending April 30	
	1941	1942
Resigned	299	211
Dropped	582	484
Total	881	695

Table IV shows the number of applications received from enrolled students and others annually for the past five years. It shows a continuous increase each year. Since applications received during the fiscal year are not all acted upon at the close of the fiscal year, there is no direct check between Tables III and IV. The Branch counselors have co-operated with the committee by writing to graduates and using their influence to procure their applications. The Section membership committees receive from headquarters the cards of graduates residing in their territory and endeavor to interview them with respect to membership.

Table III. Membership Statistics for Fiscal Year Ending April 30, 1942

	Honorary Member	Fellow	Member	Six-Year Associate	Associate	Increase	Total
Membership on April 30, 1941	8	778	4,650	5,890	6,560		17,886

Table IV. Number of Applications Received From Enrolled Students and From All Others

Year Ending April 30	Students	All Others	Total
1942	971	1,031	2,002
1941	887	1,011	1,898
1940	911	918	1,829
1939	849	872	1,721
1938	739	932	1,671

Table V. Number of Enrolled Students as of April 30

Year	New Applications	Renewals	Total
1942	2,585	3,377	5,962
1941	2,351	3,188	5,539
1940	2,525	2,992	5,517
1939	2,271	2,971	5,242
1938	2,428	2,609	5,037

Table VI. Number of Members in Section Territory Reinstated

August 1, 1941 to April 30, 1942	275
Year beginning August 1, 1940	383
Year beginning August 1, 1939	302
Year beginning August 1, 1938	354
Year beginning August 1, 1937	325

Table VII. Status of Membership Dues as of April 30

Year	Total Membership	Members Fully Paid	
		Number	Per Cent
1942	18,944*	16,595**	87.5
1941	17,886	15,777	88.2
1940	17,213	14,997	87.1
1939	16,605	14,371	86.5
1938	16,078	14,127	87.9

* Of the 18,944 members reported for April 30, 1942, 2,349 were not fully paid. Of this number, 327 names are being carried upon the membership rolls, in an inactive status, in accordance with the resolutions adopted by the Board of Directors in the interest of members in the military service of the United States or allied countries, or members located in such countries unable to remit membership dues at this time. The remainder comprises

1. Members owing dues to April 30, 1941..... 514
2. Members owing dues to April 30, 1942.....1,508 (During the period May 1 to May 20, 1942, 316 members have paid dues to April 30, 1942, reducing the number not fully paid to 1,192.)

** Including 733 Members for Life.

Table V shows data on the number of enrolled students and new applications therefrom for five successive years ending 1942. The improvement in 1942 is especially encouraging.

Tables VI and VIII show additional data on membership which are self-explanatory.

The membership committee continued the organization adopted in the preceding year which provided an advisory subcommittee, comprising committee members within easy reach of New York and thus able to hold more frequent meetings than the whole committee, and a research subcommittee to which were referred committee problems requiring study and research. This organization has been found excellently adapted to the membership committee, and permits of holding but one meeting of the committee as a whole, during the winter convention, when a good attendance is assured.

The Membership Committee Guide, a pamphlet prepared and distributed in the preceding year, which outlines recommended procedure for the conduct of Section membership committee work, has been found very helpful to Section membership committees.

In June 1941, a letter was written to each of the newly elected Section chairmen suggesting the early appointment of Section membership committees, in order that such committees can get an early start. This letter was well received by Section chairmen, and undoubtedly aided in getting membership work started early during the current committee year. This is important because of the time required to get committees organized and working, and the shortness of the period when most effective work can be done.

The research subcommittee has studied

Table VIII. Record of AIEE Membership

Year	Total May 1	Year	Total May 1	Year	Total May 1
1884	71	1905	3,460	1925	17,319

many problems during the year, the solution of which has contributed to the effectiveness of committee work. One example was its consideration of Doctor Sorensen's suggestion that an effort be made to re-interest members who have developed beyond the "design engineering" stage of their careers and who are now in managerial and executive positions. The result was a letter written to all Institute vice-presidents, District secretaries, and Section chairmen, by the chairman of the Sections committee, soliciting their assistance in a well-defined program for dealing with this problem.

In bringing the advantages of membership to the attention of desirable candidates for admission to the Institute, and in discussions with members about to drop their membership in the Institute, committee members have found that frequently the most effective appeal is that which places emphasis upon the value of the Institute as the national organization of the electrical engineering profession. In relation to present Institute members, and considering the substantial losses each year, it appears that there is opportunity to keep members better informed as to the work and accomplishments of the Institute as a national organization. This problem has also been studied by the research subcommittee and some suggestions have been made for the consideration of the board of directors.

BOARD OF EXAMINERS

The board of examiners held 11 meetings during the past year, averaging about two and one-half hours each, and acted upon 3,662 cases, divided as shown in Table X.

During the past year the board has had the opportunity to put to a practical test the "invitational method" applying to transfer to Fellow grade. This method was recommended by the examiners in December 1940. The first transfers were presented under this procedure in October 1941, and to date 13 cases have been considered, all receiving favorable recommendations. In the opinion of the examiners, all difficulties previously inherent in the Fellow transfer procedure thus have been cleared up.

A survey of the situation with regard to transfer to Member does not under present conditions seem to call for any alteration in the long-established application procedure followed in such cases. The record of the current year shows that of the 246 cases coming before the board only 14 failed to receive a favorable recommendation.

A change in procedure applying to re-elections to Member and Fellow was also put into effect during the past year. Up to April 1941, it had been customary to require applicants for re-election, out of the Institute for more than five years, to supply a new set of references. This requirement was waived in favor of a requirement that all re-election cases be posted in *Electrical Engineering* for a period of one month before formal action is taken, in order to provide for the filing of any possible objections based on ethical grounds, as, except for such ethical objections, a man is always considered eligible for re-election to the grade formerly held.

HEADQUARTERS COMMITTEE

In accordance with a request from the board of directors, the committee recommended rules governing the use of AIEE headquarters rooms for meeting purposes. The rules were adopted by the board in January.

INSTITUTE POLICY COMMITTEE

The functions of the committees on economic status of the engineer and legislation affecting the engineering profession were consolidated with those of the Institute policy committee, to be carried out by that committee through subcommittees. During the year, the committee reported to the board of directors on several matters which had been referred to it.

COMMITTEE ON PLANNING AND CO-ORDINATION

A meeting of the committee was held at Institute headquarters in New York on January 27, 1942, at which, after careful consideration and thorough discussion of the probable effects of the war upon the summer convention, the members present unanimously adopted the following recommendations to the board of directors:

1. That the 1942 summer convention be held in Chicago as planned.

2. That the summer convention and technical program committees make it a working convention, with the understanding that the resolution on "summer convention policy" adopted by the board of directors on November 12, 1920, be disregarded in this case.

3. That the summer convention and technical program committees be requested to recommend the most desirable length of program.

At this meeting, the committee considered all requests from District and Section officers for national conventions and District meetings in 1943, and recommended to the board of directors the following schedule of meetings:

Winter convention, New York, N. Y., January 25–29

Summer convention, Cleveland, Ohio, June 21–25

Pacific Coast convention, about September 1; Pacific Coast Districts to be requested to give further consideration to the selection of the most desirable location.

District meetings—Tentative approval given to the following, subject to further review by the District committees or by the board of directors if conditions make it desirable:

North Eastern District (1), Providence, R. I., spring

Southern District (4), Virginia

South West District (7), Kansas City, Mo., spring

All of these recommendations were approved by the board of directors on January 29, 1942.

The committee had, previous to the meeting, considered the request of the Vancouver Section that the 1942 Pacific Coast convention be held in Vancouver, B. C., and, having consulted the vice-presidents of the three Districts concerned, recommended to the board of directors that the convention be scheduled in Vancouver for

September 9–11. This recommendation was approved by the board on October 24, 1941.

COMMITTEE ON CODE OF PRINCIPLES OF PROFESSIONAL CONDUCT

The committee still awaits advice from the joint committee on code of ethics sponsored by Engineers' Council for Professional Development, which has been delayed in its work some four months by the illness of its chairman who also is chairman of this committee. It now is hoped to have completed by the joint committee before the summer is over a report, which then can be considered by the AIEE committee. In association with this, the ECPD committee on professional recognition is endeavoring to formulate a statement of the principles which underlie a code of ethics and which give to ethics a fundamental influence on a profession.

The chairman of the AIEE committee while still ill received a written charge of unethical practices made against an engineer by another engineer, and this will shortly be circulated for consideration by all members of the committee on code of principles of professional conduct.

COMMITTEE ON CONSTITUTION AND BYLAWS

The work of this committee has been limited to a few routine changes in the bylaws. There has been no change in the constitution.

Sections 65, 74, and 83 were modified or deleted in keeping with the action of the board of directors, taken at its meeting of August 8, 1941, to consolidate the work of the committee on economic status of the engineer and the committee on legislation affecting the engineering profession into that of the Institute policy committee.

Section 92 was modified as to date only to make it consistent with the present rules of the John Fritz Medal board of award.

COMMITTEE ON RESEARCH

The committee is now in its second year as a general committee of the Institute rather than a technical committee. As in the preceding year, the principal activity has been that of studying the program of the Engineering Foundation research projects sponsored by the Institute.

One of these, research on the stability of impregnated-paper insulation, project 66, which has been under way for some years at the Johns Hopkins University under the immediate direction of Doctor J. B. Whitehead, will be terminated for the time being at the end of the current year. This termination does not mean that all study desirable regarding this question has been completed, but it does mean that the work is well under way with an indication as to how future work should be done by those who are particularly interested in this problem as it applies to the business of manufacturing apparatus using impregnated-paper insulation. Also, since this research does not have direct bearing upon any war activity, it is believed that it would not be wise to continue it at present.

Another research, on insulating oils and cable saturants, project 74, under way at the Massachusetts Institute of Technology under the immediate supervision of Professor J. C. Balsbaugh, is somewhat newer than project 66 and is now operating on what might be called a production basis. It is recommended that this project be continued at least another year.

The Institute also sponsors jointly with the American Welding Society an extensive welding research program of the Engineering Foundation. This program is so actively supervised by the American Welding Society that the Institute has not undertaken a careful review of it. This does not indicate any lack of interest in electric welding, a science at present so vital to many of our war production activities.

In order that the committee on research may keep in close touch with the technical committees of the Institute and be of service to them when their work indicates that those committees should provide some research program, a research officer, so to speak, has been appointed in each of the technical committees. It is intended that this officer shall be the contact representative between his committee and the committee on research.

Perhaps the one acute problem facing us just now is the production of jewels for meter bearings. This is not definitely an electrical-engineering problem, but jewels for meter bearings are of such great importance to the whole electrical industry that any suggestion leading to the development of a supply of them will be of value.

Should the national situation remind any Institute member of things the committee on research should do, information regarding those recommendations will be welcome and the committee will do its best to turn all promising suggestions into active programs.

COMMITTEE ON SAFETY

The committee has continued its effort to encourage the Student Branches to hold meetings on safety. A circular letter was sent to each Student Branch again at the beginning of the autumn term urging them to hold meetings on safety and suggesting methods of arranging for interesting discussions. Another bulletin was sent at a later date informing them how to borrow two instructive motion-picture films for presentation at meetings on safety. There has been co-operation with the National Safety Council which has conducted a campaign on safety among the colleges.

A survey of the papers published in recent years on electrical safety was undertaken with the result that the committee has in preparation a bibliography of papers and articles on the subject that have been published during the past ten years.

At the suggestion of the committee, there was published in the September 1941 issue of *Electrical Engineering* a paper by G. S. Lawler, entitled "Fires of Electrical Origin in Factories," which had been presented previously at a meeting of the Lynn Section. In this paper, Mr. Lawler emphasized the importance of proper maintenance of electrical apparatus and equipment in prevention of fires and accidents. The committee believes that present war conditions make it more important than ever that electrical installations be maintained in good order.

The committee plans to continue active attention to these and other problems now before it.

Standards

STANDARDS COMMITTEE

While the past AIEE standards year has not been marked by any radically new developments, there was presented to the committee for action a greater-than-normal number of projects. This increase in activity, a continuation of last year's accelerated program, can of course be traced to wartime industrial conditions. The various standards co-ordinating committees and the technical committees of the Institute were equally responsible as the agencies for carrying out this growing program.

Eight projects were approved by the standards committee for publication, as follows:

Standards for Wet Tests, Revised Standards for Measurement of Test Voltages in Dielectric Tests, Revised Standards for Railway Motors, Rating of Electrical Apparatus for Short-Time and Intermittent Duty, Fuses Above 600 Volts, Capacitance Potential Devices, Test Code for D-C Machines, and Test Code for Single-Phase Motors.

The following projects are in various stages of committee development:

Guiding Principles for Selection of Reference and Limiting Values for Standards, Standards for Neutral Grounding Devices, Revised Standard for A-C Power Circuit Breakers, Revised Standard for Lightning Arresters, Revised Report on Standards for Mercury-Arc Rectifiers, Test Code for Impulse Measurements.

The American Standard "Definitions of Electrical Terms," defining over 4,000 electrical and allied terms, is now in the hands of the printer. In furtherance of the desire of the American Standards Association Sectional Committee on definitions to obtain the widest possible distribution for this publication, the AIEE directors authorized a minimum sales price of $1 per copy. This price was made possible only through a quantity production order for 25,000 copies. A national sales campaign is planned, which it is hoped will place not only the entire first edition, but will also require a quantity reprint. Individuals and organizations active in the electrical and allied fields are to be asked to cooperate. It is the belief of those who have given much time and thought to the definitions development that only through placement in the hands of all interested individuals can there be obtained a recognition of the real value inherent in the glossary and a justification for the immense number of man-hours spent in its development.

Two other matters of interest also came to a head during the year: the standards manual, and the standards numbering system. The manual was approved in final revised form and it is hoped will prove of great service in explaining the intricacies of standardization procedure and a valuable guide in future activities.

A study of the numbering systems used

by AIEE and ASA showed that it is impractical to select any system that will eliminate all inconsistencies. It also became evident that most of the present difficulties will eventually disappear.

The activities of Institute representatives on ASA sectional committees were continued, and in some cases considerably accelerated because of the war effort. Replacement of representatives was found necessary in a number of cases, largely because of occupational shifts. The organization of a new sectional committee on electric fences is now under way. All international standardization activity as carried on by the International Electrotechnical Commission is at a practical standstill as a result of the war. However, it is planned to push standardization as it affects South and Central America. One step in this direction is the proposed translation of Standards into Spanish and Portuguese.

UNITED STATES NATIONAL COMMITTEE OF THE INTERNATIONAL ELECTROTECHNICAL COMMISSION

The work of the International Electrotechnical Commission, because of the present international situation, has been practically suspended. The central office is being maintained, however, and continues to receive mail at its old address in London, although its valuable records have been moved to a place of safety "for the duration." The United States National Committee of the IEC also is keeping its organization intact and will continue to meet annually so that, as soon as circumstances permit, it will be possible to resume activities.

The USNC at its annual meeting in December 1941 re-elected its officers: E. C. Crittenden, president; L. F. Adams and H. S. Osborne, vice-presidents; Doctor C. H. Sharp, honorary president.

At its annual meeting, the USNC gave further consideration to the desirability of assisting in developing standardization work among the countries of North and South America. As a result of this consideration, the USNC decided to discharge its committee on the subject since the committee's exploration had shown that various other organizations were planning to undertake co-operative work with South American countries and that it seemed best for the USNC to abandon its efforts and to assist where it could the work of other agencies, particularly that of the ASA.

Technical Committees

COMMITTEE ON AUTOMATIC STATIONS

The bibliography on automatic stations covering the period 1932–1940 has been extended to cover 1941, plus a few additional references for 1940, and is now in the hands of the publication committee.

The committee prepared a questionnaire on a-c automatic reclosing equipment applying to stub feeders only. A subcommittee has distributed copies throughout the various Districts, including Canada, and the material collected from this survey will be included in a future report.

A questionnaire on pilot conductors has been received by the relay subcommittee of the committee on protective devices, with which the questionnaire was jointly issued. That subcommittee has issued a preliminary report pertaining to that section of the survey in which it is interested. It is expected that in the near future certain portions of the collected material will be turned over to the committee on automatic stations for classifying the data in which it is interested.

COMMITTEE ON EDUCATION

At the 1941 summer convention, the subcommittee on student guidance reported on its work during the past year. From a questionnaire sent to all the Institute Sections 59 replies were received, of which 20 indicated that those Sections had been carrying on some form of high-school student guidance during the previous year. Of the other 39, 32 stated that they were interested in this kind of work and would welcome suggestions as to how to proceed.

The subcommittee on student guidance was continued for the present year, and an attempt has been made to help those Sections which are interested in carrying on guidance work for the benefit of high-school seniors. The results of this work have not yet come in.

The committee held an informal meeting at the time of the South West District meeting in October 1941, and decided to sponsor an educational session at the winter convention the following January. Three papers were secured and approved for presentation at this convention—one of them for publication in the *Transactions*. The presentation of the papers brought out much interesting discussion.

During the 1942 winter convention, the committee held its annual meeting and discussed the problems of education in the light of the present war emergency. Any move toward the shortening of the academic time spent by students in courses in electrical engineering and any abbreviation of the net content of courses were deplored. The speeding-up of graduation by the elimination of vacations was approved. A resolution to this effect was transmitted to the board of directors, and was approved at the next meeting of the board.

After this meeting, the difficulty of carrying on inspection trips for the benefit of engineering students during the war emergency was discussed and the possibility of showing motion pictures of industrial plants instead was mentioned. A subcommittee on inspection trips was appointed to look into the matter of accumulating information about films that might be secured.

The committee decided to sponsor a discussion session on education at the 1942 summer convention in Chicago, Ill., but to ask for no formal papers on account of the difficulty of getting them written during the war emergency.

For the North Eastern District meeting, the committee approved one paper on the subject of vocational education.

COMMITTEE ON ELECTRICAL MACHINERY

The committee held two meetings during the year, one at the summer convention in Toronto in June 1941, and one at the winter convention in New York in January 1942, at which technical sessions at conventions were discussed and the work of the committee and its subcommittees was reviewed. Plans were made for the 1942 summer convention, to sponsor one symposium on emergency overloading of apparatus and one on mercury-arc rectifiers and their application.

The subcommittee on synchronous machinery has progressed in its work on the revision of the Test Code on Synchronous Machinery and is planning on having the revision prepared and ready for review by June 1942.

The transformer subcommittee continued its co-operation with the ASA committee in the review of the revised ASA Standards on transformers. Papers have been presented and are being prepared for presentation on overloading of transformers for emergency conditions.

The subcommittee on test codes for single-phase motors completed its work on the test code which was submitted to the standards committee. It was issued by the standards committee in November 1941 as the AIEE Proposed Test Code for Single-Phase Motors.

The Test Code for D-C Machines, submitted last year to the standards Committee, was issued by that committee in July 1941.

The subcommittee on rectifiers has, among other things, been studying definitions and a paper was prepared for presentation at the North Eastern District meeting with a view toward unifying terminology. This is of some importance as common practice has not been uniform in terms and meanings in all cases.

The subcommittee on insulation resistance has started work with the object of producing a standard on methods of measuring insulation resistance and a guide for the interpretation of the results obtained.

The committee sponsored one session at the summer convention in 1941 at which five papers on miscellaneous subjects were presented. At the Pacific Coast convention, one paper approved by the committee was presented. At the South West District meeting, one session was sponsored jointly by the committees on electrical machinery and power generation, and several papers on motors were presented. One session on power and machinery and a conference on mercury-arc rectifiers were arranged for the North Eastern District meeting.

COMMITTEE ON ELECTROCHEMISTRY AND ELECTROMETALLURGY

As a result of the pressure of work incident to the war there has been little committee activity during the year. At the meeting held on January 26, 1942, the progress report of the subcommittee on voltage transients in arc-furnace circuits was discussed, and it was voted to continue the study being carried on by the subcommittee. It was requested that any instances of severe transients or short circuits on arc-furnace circuits be reported to N. R. Stansel, subcommittee chairman.

The need for standardization of transformers for electric-arc-furnace operation

was also presented. On motion duly approved, President Prince was requested to appoint a joint subcommittee consisting of representatives of the committee on electrochemistry and electrometallurgy and the transformer section of the committee on electrical machinery to consider the standardization of electric-arc-furnace transformers.

The rapidly increasing demand for electric power by electrothermal and electrochemical plants was discussed. It was pointed out that within the next two to three years these operations will require an additional 20 billion kilowatt-hours per year in the production of aluminum, magnesium, chlorine, stainless steel, and similar war materials.

COMMITTEE ON INSTRUMENTS AND MEASUREMENTS

Two major committee projects were completed. The report on "Telemetering, Supervisory Control, and Associated Circuits," prepared by a joint subcommittee of the committees on automatic stations and on instruments and measurements has been issued in pamphlet form. This encyclopedic report classifies and tabulates the characteristics of the various types of telemetering equipment and should form a useful basis of any future standardization. The report on "Progress in the Art of Metering Electric Energy" prepared by the subcommittee on watt-hour meters was published in serial form in *Electrical Engineering*, beginning with the September 1941 issue and concluding with the December issue. The report is now available in pamphlet form also. It constitutes a complete and authoritative history of the development of the d-c and induction types of watt-hour meters, and includes also a short history of the development of the demand meter.

Technical sessions on instruments and measurements were held at the 1941 summer convention in Toronto and at the 1942 winter convention, at which five, and four papers, respectively, were presented. The committee also sponsored a group of papers stimulated by its subcommittee on dielectric measurements in the field and presented at the session on insulation testing at the 1941 summer convention. The pressure of military work and the confidential nature of new developments probably will seriously curtail the output of technical papers in the immediate future.

In view of the necessity for conserving our energies, a questionnaire was circulated early in the year to stimulate a critical examination of the various standardization activities of the committee. At the fall meeting, it was decided to leave certain lines of work in abeyance and to concentrate on the more pressing problems.

The subcommittee on the revision of AIEE Standard No. 4 has prepared an addition to the table of sphere-gap voltages for 6.25- and 12.5-centimeter spheres which will permit their use up to spacings equal to their diameters. This has been approved by the committee on instruments and measurements and by the standards committee. This subcommittee which is identical in personnel with the corresponding ASA Sectional Committee, remains in readiness for any future standardization in this field.

The subcommittee on definitions has been active in revising certain definitions for the ASA "Dictionary" *C*42 and in securing agreement between these definitions and those used in the "Code for Electricity Meters" and the "Meterman's Handbook."

The subcommittee on current transformers has participated in the revision of section 4 of ASA Standard *C*57 for Transformers, Regulators, and Reactors, in the light of the year's experience with this "Proposed American Standard."

A new subcommittee was appointed to prepare a master code for temperature measurements and has made very good progress.

More recently another subcommittee has been formed to study the report on standards for electrical recording instruments, AIEE No. 40, and to revise it, if necessary, in order that it may be advanced to full standard status.

The committee continues to be represented by liaison members on several other technical committees of the Institute.

COMMITTEE ON MARINE TRANSPORTATION

The activities of this committee have been very greatly curtailed because of war conditions and pressure of work upon all members engaged in shipbuilding and associated industries.

A meeting was held on December 12, 1941. Several changes in Standard No. 45 were approved by the committee, and an addendum issued for the changes approved since the issue of the addenda dated March 20, 1941. The committee has endeavored to keep this Standard up to date to conform to the best practice in shipbuilding. War conditions and scarcity of various materials have necessitated deviation from materials specified therein. The committee decided that such temporary changes should not be incorporated in Standard No. 45. This matter is one that the various manufacturers can best handle to suit their own particular cases.

The subcommittee on wire and cables has been active, and has done considerable work on suggested revisions proposed by the Insulated Power Cable Engineers Association. The purpose of the proposed revisions is to bring the specification for wire and cables in Standard No. 45 more nearly in conformity with the IPCEA standards.

A special subcommittee was appointed to confer with the American Bureau of Shipping on matters relating to the general scope and purpose of Standard No. 45. This matter will require considerable study by the subcommittee before it can be presented to the main committee for consideration. It is doubtful if final action can be taken this year, and it will probably be carried over into the next fiscal year.

COMMITTEE ON POWER TRANSMISSION AND DISTRIBUTION

The committee is now completing the second year of its activities under the new organization with four main subcommittees as follows: substations, transmission, distribution, and general systems. Each subcommittee functions through working groups, the number of which depends on the subject problems coming within its scope.

During the past year, the main committee's activities have been confined largely to sponsoring technical sessions at conventions and reviewing technical papers. The committee sponsored three complete sessions at the winter convention, and likewise is planning three technical sessions at the 1942 summer convention. At the winter convention, one session organized by the committee was devoted to the broad and timely subject, "Distribution Systems in Wartime." Another session was devoted to lightning. One session wholly on cables, and another on lightning, are planned for the summer convention. Other papers sponsored by the committee cover subjects associated directly with the transmission and distribution art, while some cover fields of interest to other committees and are therefore under joint sponsorship.

The proposed revision of Standard No. 41, Insulator Tests, issued in March 1941, is being worked on at the present time with the expectation that it will soon be offered for approval as an AIEE standard. So few comments have so far been received that it is believed this standard can be offered for approval shortly.

The activities of the main committee have been considerably restricted on account of the war conditions; and, as there have not been in evidence problems of immediate concern or importance apparently requiring attention of the committee, the calling of frequent meetings has not seemed justified. Likewise, the work of the subcommittees and working groups has been considerably restricted on account of present wartime conditions. A number of subjects of interest are being considered by these groups, but sufficient progress has not yet been made to report on now.

As many members of the committee are closely associated with problems arising from United States war activities, there has not appeared justification for making heavy demands on the time of these men for committee work which is not mandatory.

COMMITTEE ON PRODUCTION AND APPLICATION OF LIGHT

The committee has continued to keep members of the Institute informed on the latest developments in illuminating engineering, principally through the sponsorship of conferences at District meetings and national conventions and by obtaining articles from qualified authors on illumination subjects for publication in *Electrical Engineering*.

All of these activities have been intensified this year, and plans are now under way to extend them further, especially in those lighting fields which are vital to national defense. A complete report on a conference on civilian-defense lighting held during the 1942 winter convention appeared in *Electrical Engineering* for March 1942, pages 155–6.

A conference on lighting for production is now under consideration for the summer convention in June 1942. Prominent speakers from Canada and the United States will be asked to prepare discussions on this subject which is vital to the defense of each country.

In addition to reviewing all papers on the subject of lighting which are presented for consideration by the technical program committee, and selecting timely lighting subjects and encouraging competent authors to prepare articles for *Electrical Engineering*, this committee also sponsors in *Electrical Engineering* brief summaries and photographs of notable lighting installations.

COMMITTEE ON PROTECTIVE DEVICES

The committee held three meetings during the year and probably will hold another at the 1942 summer convention. Attendance was good, and the discussions dealt mainly with new and revised standards, apparatus insulation levels, temperatures for various types of switchgear, subcommittee reports on subjects under consideration, and papers proposed for technical sessions.

In keeping with the preparedness and war effort, the committee has attempted to bring to completion as rapidly as possible work on the various Standards under its jurisdiction. This appeared very desirable and necessary in order that production during the war period can be based on Standards which reflect proper requirements and present practice. Two new Standards (Nos. 31 and 32) were prepared, approved, and transmitted to the standards committee with recommendation for approval and publication as AIEE Standards. Four Standards (Nos. 19, 22, 27, and 28), which had been issued the previous year for trial use, were completely reviewed and recommended revisions approved. Two other Standards (Nos. 24 and 25) were reviewed. One was recommended to be left unchanged for the time being and work on revision of the other has not been completed.

The major work of the committee was divided among subcommittees: on circuit breakers, switches, and fuses; fault-current limiting devices; lightning arresters; and relays.

The reports of the subcommittees indicate that very substantial progress has been made, especially when it is realized that all members have had unusually large demands on their time for war purposes in connection with their regular work. Consequently, their participation in committee activities, while active and co-operative, have been under somewhat of a handicap.

The following three reports covering a decade of progress in the art were completed and published in *Electrical Engineering:* "Ten Years of Progress in Circuit Interrupters" November 1941; "Ten Years of Progress in Relaying," December 1941; "Ten Years of Progress in Lightning Protection," April 1942.

The committee also has been responsible for the preparation of two extensive bibliographies in its field. One, covering relay literature for the period 1927–39, was prepared by the relay subcommittee and issued as a special Institute publication in July 1941. The second, a comprehensive bibliography on circuit-interrupting devices, including circuit breakers, enclosed switchgear, air switches, bus bars, and fuses, and covering the period 1928–40, is currently in process of publication.

The committee sponsored 13 papers at the 1941 summer convention, 7 at the Pacific Coast convention, 2 at the South West District meeting, one at the Southern District meeting, 19 at the 1942 winter convention, and 1 at the North Eastern District meeting.

The future work of the committee may logically follow along lines of endeavor similar to those of the past. In view of the industry needs, every effort should be made to complete at an early date the proposed standard on distribution-type protector tubes and the revision of Standard No. 25, Fuses Above 600 Volts, as well as the technical report dealing with the subject of selection of neutral-grounding-device impedance.

Awards

COMMITTEE ON AWARD OF INSTITUTE PRIZES

Four national and 11 District prizes were awarded for papers presented during the calendar year 1941 and for the student papers presented during the academic year ending June 30, 1941.

A large number of eligible papers, which were of good quality, were considered, and in determining the awards for the national best paper prizes and the initial paper prize the committee had the benefit of the gradings and recommendations of the technical committees which reviewed the papers. In addition to the four papers awarded national prizes, eight other papers were given honorable mention.

The changes made in the rules on award of "National and District Prizes," issued in the new edition of January 1941, have been in effect for more than an entire year, and have been found to be working satisfactorily.

EDISON MEDAL

The Edison Medal, which is awarded by a committee composed of 24 members of the Institute, was awarded for 1941 to Doctor John Boswell Whitehead, "for his contributions to the field of electrical engineering, his pioneering and development in the field of dielectric research, and his achievements in the advancement of engineering education," and was presented on January 28, 1942, during the winter convention. The medal may be awarded annually for "meritorious achievement in electrical science, electrical engineering, or the electrical arts."

LAMME MEDAL

The Lamme Medal committee awarded the medal for 1941 to Forrest E. Ricketts, vice-president, Consolidated Gas Electric Light and Power Company, Baltimore, Md., "for his contribution to the high reliability of power-supply systems, especially in the design of apparatus for selective relaying and circuit reclosure." Arrangements are being made for the presentation of the medal at the summer convention in Chicago, Ill., June 22–26, 1942. The medal may be awarded annually to a member of the AIEE "who has shown meritorious achievement in the development of electrical apparatus or machinery."

JOHN FRITZ MEDAL

The John Fritz Medal board of award, composed of representatives of the American Society of Civil Engineers, American Institute of Mining and Metallurgical Engineers, American Society of Mechanical Engineers, and AIEE, awarded the 38th medal (for 1942) to Everett Lee DeGolyer, consulting petroleum engineer, Dallas, Tex., and a past president of AIME, for "pioneer work in the application of geophysical exploration to the search for oil fields."

HOOVER MEDAL

The Hoover Medal was established through a trust fund created by a gift from Conrad N. Lauer, and is to be awarded periodically "to a fellow engineer for distinguished public service" by a board representing the national societies of civil, mining and metallurgical, mechanical, and electrical engineers. The fifth medal, for 1941, was awarded to D. R. Yarnall, cofounder and chief engineer, Yarnall-Waring Company, Chestnut Hill, Pa., a member of ASME and a past president of United Engineering Trustees.

ALFRED NOBLE PRIZE

This prize, established in 1929, consists of a certificate and a cash award from the income from a fund contributed by engineers and others to perpetuate the name and achievements of Alfred Noble, past president of ASCE, and of the Western Society of Engineers. It may be made to a member of any of the co-operating societies, ASCE, AIME, ASME, AIEE, or WSE, for a technical paper of particular merit accepted by the publication committee of any of these societies, provided the author, at the time of such acceptance, is not over 30 years of age. The award for 1940–41 was presented to R. F. Hays, Jr. (A'36), Sperry Gyroscope Company, Garden City, N. Y., for his paper "Development of the Glow Switch" (published in AIEE *Transactions*, volume 60, 1941, May section, pages 223–6).

WASHINGTON AWARD

The Washington Award for 1942 was bestowed upon William Lamont Abbott (F'13) retired chief operating engineer, Commonwealth Edison Company, Chicago, Ill., and a past president of both ASME and WSE, "for advancing the standards of the engineering profession for service to higher education for aiding combustion research," and was presented to him at a dinner on February 26, 1942. This award may be made annually to an

engineer by the commission of award composed of nine representatives of the Western Society of Engineers and two each of ASCE, AIME, ASME, and AIEE.

CHARLES LE GEYT FORTESCUE FELLOWSHIP COMMITTEE

The committee met in March to decide upon the award of the fellowship for the year 1942–43. In view of the very small number of candidates, with a further possibility that any one of them might be called for some form of service with the government, it was decided that no fellowship would be awarded this year. This action is the same as was taken last year for similar reasons.

Joint Activities

UNITED ENGINEERING TRUSTEES, INC.

This organization is the corporate body which holds title in the name of the four Founder Societies to their joint physical properties, namely, the Engineering Societies Building, the Engineering Societies Library, and the endowment funds of the Engineering Foundation. It operates and manages the Engineering Societies Building, and administers certain joint activities of the four Founder Societies.

The building is fully occupied by the Founder Societies and associates. During the year, certain changes were made to improve the services to members of the societies and others, notably improvement in the illumination of the library by the installation of fluorescent lamps, changes in elevator doors on several floors, reconstruction of one floor to provide a greater number of offices, and the change of the electricity supply system from direct to alternating current.

An abstract of the annual report of the corporation for the year which ended September 30, 1941, appeared on pages 56–57 of *Electrical Engineering* for January 1942.

ENGINEERING FOUNDATION

The Engineering Foundation is a joint organization of the national societies of civil, mining and metallurgical, mechanical, and electrical engineers established for "the furtherance of research in science and engineering, and the advancement in any other manner of the profession of engineering and the good of mankind." It assists in a wide range of research projects of interest to science, engineering, industry, and the general public, each project being under the sponsorship of one of the Founder Societies.

Under the sponsorship of the Institute, the Foundation has continued to support the research on stability of impregnated-paper insulation, at the Johns Hopkins University, the research on insulating oils and cable saturants, at the Massachusetts Institute of Technology, and the welding research, the latter under joint sponsorship with the American Welding Society.

A comprehensive abstract of the annual report of the Engineering Foundation for the year which ended September 30, 1941, appeared on pages 57–59 of *Electrical Engineering* for January 1942.

ENGINEERING SOCIETIES LIBRARY

The Engineering Societies Library, which was formed by combining the separate libraries of the four national societies of civil, mining and metallurgical, mechanical, and electrical engineers, and the preparation of a composite card catalog, probably constitutes the best collection of its type in the United States.

On September 30, 1940, the library had 152,263 volumes, 7,755 maps, and 4,492 searches. Books and pamphlets totaling 3,021 were received during the year ending at that time. Current issues of 1,124 periodicals were received. About 20,000 entries were added to the index of periodicals, which now contains over 260,000 cards.

Special services rendered by the library include: photoprints, searches, abstracts, translations, bibliographies, book loans by mail, and others. The library board has been considering means by which members might be more adequately informed regarding the services available.

An abstract of the annual report of the library appeared on pages 59–60 of *Electrical Engineering*, January 1942.

EMPLOYMENT SERVICE

Operating as an incorporated non-profit-making organization, the Engineering Societies Personnel Service, Inc., assists members of the Founder Societies desiring to secure new positions, and conversely assists employers searching for engineers. Nonmembers may receive such assistance when positions available cannot be filled by members.

Offices are operated in New York, N. Y., Detroit, Mich., Chicago, Ill., and San Francisco, Calif., with the co-operation of the Engineering Society of Detroit in that city, the Western Society of Engineers in Chicago, and the Engineers Club of San Francisco in that city.

The service is supported by the joint contributions of the societies and the individuals who secure positions. An analysis of registration and placement records as reported to the national societies is given in table XI.

ENGINEERS' COUNCIL FOR PROFESSIONAL DEVELOPMENT

This Council, organized in 1932 to engage in activities leading toward the enhancement of the professional status of the engineer, includes three representatives of each of the eight participating organizations, which are the national societies of civil, electrical, mechanical, and mining and metallurgical engineers, the Society for the Promotion of Engineering Education, the National Council of State Boards of Engineering Examiners, and the Engineering Institute of Canada. Its principal activities have been carried on by four committees: student selection and guidance, engineering schools, professional training, and professional recognition.

Including the actions on engineering curricula taken on October 30, 1941, the record is:

Total curricula submitted, including reinspections	896
Accredited	460
Accredited provisionally	105
Not accredited	167
Reinspections with no change in status	132
Action pending	6

A comprehensive report on the annual meeting held on October 30, 1941, and a complete list of accredited curricula appeared on pages 606–10 of *Electrical Engineering* for December 1941.

JOINT CONFERENCE COMMITTEE

Upon recommendation of the committee on planning and co-ordination, the board of directors authorized the president and national secretary to join with like officers of the other Founder Societies in an informal conference committee to meet whenever deemed advisable to consider joint efforts in national defense and other matters. The committee met in Indianapolis, Ind., Washington, D. C., Montreal, Que., and Roanoke, Va.

In accordance with its recommendations, the societies organized a joint committee on postwar planning and a joint committee on

Table XI. Analysis of Employment Service

inter-American engineering co-operation. It considered various other matters of interest to members of the several societies.

REPRESENTATIVES

In addition to the many divisions of its work represented by its own general and technical committees, the Institute participates in a wide range of activities of interest and importance to engineers and others through its representation upon about 30 joint committees and national organizations.

A list of representatives was published in the September 1941 issue of *Electrical Engineering* and in the 1942 Year Book.

Appreciation

On behalf of the membership, the board of directors expresses its sincere appreciation of the many important contributions to Institute activities made by the national committees and the District, Section, and Branch officers. Despite the extreme difficulties encountered during the past year, and consequent severe restrictions of time available for engineering society activities, enthusiasm for and constructive accomplishment in Institute work have continued at a high level. The continuing keen interest among the members in general has contributed substantially to the accomplishments of the Institute. The board thanks all for their interest and unselfish co-operation.

Respectfully submitted for the board of directors.

H. H. HENLINE
National Secretary

May 22, 1942

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS

Property and Restricted Funds Securities, Less Reserve for Securities of Doubtful Value, April 30, 1942

Schedule 1

	Principal Amount of Bonds or Number of Shares of Stock	Restricted Funds: Reserve Capital Fund	Restricted Funds: International Electrical Congress Library Fund	Restricted Funds: Lamme Medal Fund	Restricted Funds: Total Restricted Funds	Property Fund (Equipment Replacements)
Railroad Bonds:						
Alleghany Corporation 20 year collateral trust convertible 5%, due 1949	$15,000.00	$ 10,627.50			$ 10,627.50	
Baltimore & Ohio Railroad Company 6% refunding and general mortgage series C, due 1995 (stamped)	12,000.00	8,940.00		$4,330.00	13,270.00	
Chicago & Erie Railroad Company 5% first mortgage, due 1982	1,000.00	1,105.00			1,105.00	
Florida East Coast Railway Company 5% first and refunding mortgage series A, due 1974 (certificates of deposit)	10,000.00*	9,818.75*			9,818.75*	
New York Central Railroad Company 5% refunding and improvement mortgage series C, due 2013	6,000.00	5,742.50			5,742.50

HASKINS & SELLS
CERTIFIED PUBLIC ACCOUNTANTS

22 EAST 40TH STREET
NEW YORK

May 15, 1942

American Institute of Electrical Engineers,
33 West 39th Street, New York.

Dear Sirs:

We have made an examination of your balance sheet as of April 30, 1942, and of your recorded cash receipts and disbursements for the year ended that date. Our examination consisted of a review of the system of internal control and of the accounting procedures of the Institute and examination or tests of its accounting records and other supporting evidence by methods and to the extent we deemed appropriate. We present the following:

Balance Sheet, April 30, 1942 (Exhibit A).
Property and Restricted Funds Securities, Less Reserve for Securities of Doubtful Value (Schedule 1).

Statement of Recorded Cash Receipts and Disbursements of Operating Fund for the Year Ended April 30, 1942 (Exhibit B).

Statement of Recorded Cash Receipts and Disbursements of Property and Restricted Funds for the Year Ended April 30, 1942 (Exhibit C).

In our opinion, the accompanying Exhibit A fairly presents your financial condition at April 30, 1942, and the accompanying Exhibits B and C fairly present your recorded cash receipts and your disbursements of funds, as indicated, for the year ended that date.

Yours truly,

(Signed) HASKINS & SELLS

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS

Balance Sheet, April 30, 1942

Exhibit A

ASSETS		
Property Fund Assets:		
One-fourth interest in physical properties of United Engineering Trustees, Inc.:		
Land, buildings, and equipment (less depreciation and renewal reserve)	$385,367.94	
Funded depreciation and renewal reserve	113,080.54	
Total	$498,448.48	
Equipment:		
Library—volumes and fixtures	37,296.37	
Office furniture and fixtures (less reserve for depreciation, $24,973.05)	9,764.34	
Works of art, etc.	3,001.35	
Investment, less reserve in full $943.73—Schedule 1		
Total property fund assets		$548,510.54
Restricted Fund Assets:		
Securities—at cost, less reserve, $37,843.72 (quoted market value, $203,652.82), Schedule 1	$225,220.33	
Cash (Exhibit C)	63,751.26	
Accrued interest receivable	36.25	
Total restricted fund assets		289,007.84
Operating Fund Assets:		
Cash (Exhibit B)	$ 16,633.48	
Accounts receivable:		
Members—for dues (less reserve, $8,000.00)	10,861.98	
Advertisers	1,424.03	
Miscellaneous	4,158.44	
Accrued interest receivable	1,812.04	
Inventories:		
Transactions, etc.	1,277.25	
Text and cover paper	6,492.70	
Work in process (May issue of *Electrical Engineering*, etc.)	6,513.99	
Badges	1,345.97	
Total operating fund assets		50,519.88
Total		$888,038.26

LIABILITIES		
Property Fund Reserves		$548,510.54
Restricted Fund Reserves:		
Reserve Capital fund	$251,211.20	
Pension fund	18,000.00	
Life Membership fund	8,805.91	
International Electrical Congress of St. Louis Library fund	5,358.05	
Lamme Medal fund	4,556.83	
Mailloux fund	1,075.85	
Total restricted fund reserves		289,007.84
Operating Fund Reserves, Liabilities, Etc.:		
Accounts payable	$ 13,113.38	
Deferred income:		
Dues received in advance	4,886.98	
Entrance fees and dues advanced by applicants for memberships	659.60	
Deferred credits for other unallocated receipts	487.55	
Subscriptions for *Transactions* received in advance	45.16	
Reserve for prepaid subscriptions for *Electrical Engineering*	5,066.74	
Operating fund reserves	26,260.47	
Total operating fund reserves, liabilities, etc.		50,519.88
Total		$888,038.26

Officers and Committees for 1942–43

Officers

President

HAROLD S. OSBORNE — New York, N. Y.
(Term expires July 31, 1943)

Junior Past Presidents

R. W. SORENSEN — Pasadena, Calif.
(Term expires July 31, 1943)

DAVID C. PRINCE — Schenectady, N. Y.
(Term expires July 31, 1944)

Vice-Presidents

District

2 (To be announced)
4 J. ELMER HOUSLEY — Alcoa, Tenn.
6 ARTHUR L. JONES — Denver, Colo.
8 WALTER C. SMITH — San Francisco, Calif.
10 C. A. PRICE — Hamilton, Ont.
(Terms expire July 31, 1943)

1 K. B. McEACHRON — Pittsfield, Mass.
3 CHARLES R. JONES — New York, N. Y.
5 A. G. DEWARS — Minneapolis, Minn.
7 E. T. MAHOOD — Kansas City, Mo.
9 E. W. SCHILLING — Bozeman, Mont.
(Terms expire July 31, 1944)

Directors

MARK ELDREDGE — Washington, D. C.
C. M. LAFFOON — East Pittsburgh, Pa.
F. J. MEYER — Oklahoma City, Okla.
(Terms expire July 31, 1943)

T. F. BARTON — New York, N. Y.
M. S. COOVER — Ames, Iowa
R. G. WARNER — New Haven, Conn.
(Terms expire July 31, 1944)

L. R. GAMBLE — Spokane, Wash.
T. G. LeCLAIR — Chicago, Ill.
FRED R. MAXWELL, JR. — Pensacola, Fla.
(Terms expire July 31, 1945)

K. L. HANSEN — Milwaukee, Wis.
W. B. MORTON — Glenside, Pa.
W. R. SMITH — Newark, N. J.
(Terms expire July 31, 1946)

National Treasurer

W. I. SLICHTER — Schenectady, N. Y.
(Term expires July 31, 1943)

National Secretary

H. H. HENLINE — New York, N. Y.
(Term expires July 31, 1943)

Local Honorary Secretaries

AUSTRALIA—V. J. F. Brain, Department of Public Works, Bridge Street, Sydney, N.S.W.

BRAZIL—Richard H. Bowles, Sao Paulo Tramway Light and Power Company, Sao Paulo.

ENGLAND—A. P. M. Fleming, Metropolitan-Vickers Electric Company, Trafford Park, Manchester.

FRANCE—A. S. Garfield, 173 Boulevard Haussmann, Paris, 8E.

INDIA, NORTHERN—V. F. Critchley, 3 Abbot Road, Lahore, Punjab.

INDIA, SOUTHERN—N. N. Iengar, The Tata Power Co. Ltd., Bombay House, Bruce Street, Fort Bombay.

NEW ZEALAND—P. H. Powell, Canterbury College, Christchurch.

SWEDEN—A. F. Enstrom, Ingeniorsvetenskrapsakademien, Stockholm, 5.

TRANSVAAL, SOUTH AFRICA—W. Elsdon-Dew, P. O. Box 4563, Johannesburg.

General Committees

Executive

Harold S. Osborne, *chairman*, 195 Broadway, New York, N. Y.

E. T. Mahood, *chairman*, Southwestern Bell Telephone Company, Kansas City, Mo.
J. M. Thomson, *vice-chairman*, Ferranti Electric, Ltd., Mount Dennis, Toronto, Ont.
E. W. Schilling, *secretary*, Montana State College, Bozeman, Mont.

O. C. Brill — H. L. Hazen
M. S. Coover — S. J. Lisberger
C. A. Faust — W. B. Morton
R. M. Pfalzgraff

Ex officio

Chairmen of all Institute Sections

Standards

J. R. North, *chairman*, Commonwealth and Southern Corporation, Jackson, Mich.
A. C. Monteith, *vice-chairman*, Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa.
H. E. Farrer, *secretary*, AIEE, 33 W. 39th Street, New York, N. Y.

P. L. Alger — R. L. Jones
E. C. Crittenden — Alexander Maxwell
W. P. Dobson — S. H. Mortensen
C. M. Gilt — E. B. Paxton
R. T. Henry — Gordon Thompson

Ex officio

President, United States National Committee of the International Electrotechnical Commission
Chairmen of AIEE delegations or sole AIEE representatives on other standardizing bodies
Chairmen of working committees
Chairmen of standards co-ordinating committees
Chairmen of AIEE technical committees

Student Branches

R. G. Warner, *chairman*, 7 Alden Avenue, New Haven, Conn.
E. W. O'Brien, *vice-chairman*, 1020 Grant Building, Atlanta, Ga.
H. H. Henline, *secretary*, 33 W. 39th Street, New York, N. Y.

H. W. Bibber — A. Naeter
L. A. Bingham — B. L. Robertson
P. L. Hoover — G. H. Sechrist
Everett S. Lee — V. G. Smith
W. J. Miller — E. M. Strong
G. W. Swenson

Ex officio

Student Branch counselors

Technical Program

P. L. Alger, *chairman*, General Electric Company, Schenectady, N. Y.
F. A. Cowan, *vice-chairman*, American Telephone and Telegraph Company, 195 Broadway, New York, N. Y.
C. S. Rich, *secretary*, AIEE, 33 W. 39th Street, New York, N. Y.

H. W. Bibber — S. H. Mortensen
C. L. Dawes — W. B. Morton
M. D. Hooven — H. S. Phelps
T. A. Worcester

Ex officio

Chairmen of all technical committees, the committee on planning and co-ordination, the committee on safety, and the standards committee

Transfers

G. A. Kositzky, *chairman*, Ohio Bell Telephone Company, 750 Huron Road, Cleveland, Ohio
H. E. Farrer, *secretary*, AIEE, 33 W. 39th Street, New York, N. Y.

E. A. Crellin — J. W. Lingary
Arthur L. Jones — M. J. McHenry
F. V. Smith

Special Committee

Registration of Engineers

C. R. Beardsley, *chairman*, New York City Department of Commerce, 60 Broadway, New York, N. Y.

A. T. Campbell — T. G. LeClair
Tomlinson Fort — K. B. McEachron
N. B. Hinson — J. G. Wray

Technical Committees

Air Transportation

T. B. Holliday, *chairman*, Wright Field, Dayton, Ohio
Vernon H. Grant, *vice-chairman*, Bureau of Aeronautics, U. S. Navy Department, Washington, D. C.
S. H. Wright, *secretary*, Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa.

W. V. Boughton — E. E. Minor
H. A. Campbell — C. B. Mirick
Fred Foulon — David C. Prince
E. G. Keller — D. R. Shoults

Automatic Stations

F. F. Ambuhl, *chairman*, Toronto Hydro-Electric Systems, 14 Carlton Street, Toronto, Ont.
R. B. Arthur, *vice-chairman*, New York City Transit System, BMT Division, Brooklyn, N. Y.
A. M. de Bellis, *secretary*, Consolidated Edison Company of New York, Inc., 4 Irving Place, New York, N. Y.

A. E. Anderson — J. R. Harrington
R. F. Davis — G. S. Lunge
W. W. Edson — Perry Peterson
J. A. Elzi — C. F. Publow
L. R. Gamble — M. E. Reagan
E. E. George — G. S. Whitlow

Subcommittee Chairman

J. A. Elzi, A-C Automatic Reclosing Equipment

Basic Sciences

H. H. Race, *chairman*, General Electric Company, Research Laboratory, Schenectady, N. Y.
R. W. Ager, *vice-chairman and secretary*, Cornell University, Ithaca, N. Y.

A. S. Albright — M. J. Kelly
A. Boyajian — W. A. Lewis
J. G. Brainerd — F. C. Lindvall
H. L. Curtis — K. W. Miller
L. O. Grondahl — G. W. Penney
C. R. Hanna — Walther Richter
H. L. Hazen — M. F. Skinker
N. S. Hibshman — J. D. Tebo
J. E. Hobson — Ernst Weber

Communication

Haraden Pratt, *chairman*, Mackay Radio and Telegraph Company, 67 Broad Street, New York, N. Y.
H. A. Affel, *vice-chairman*, 463 West Street, New York, N. Y.
John Davidson, Jr., *secretary*, 463 West Street, New York, N. Y.

A. L. Albert — D. K. Lippincott
H. H. Beverage — E. T. Mahood
J. D. Booth — L. R. Mapes
R. S. Burnap — J. R. Martin
J. L. Callahan — R. G. McCurdy
D. E. Chambers — H. H. Nance
J. B. Coleman — H. H. Newell
F. A. Cowan — E. J. O'Connell
H. C. Dillingham — L. G. Pacent
D. G. Geiger — J. G. Patterson
E. E. George — John B. Russell
C. G. Grimes — E. R. Shute
Gerald C. Gross — Arthur B. Smith
E. W. Hamlin — Rothwell E. Smith
A. P. Hill — Warner T. Smith
S. B. Ingram — H. M. Turner
G. W. Janson — W. C. White
H. E. Kent — E. P. Yerkes

Domestic and Commercial Applications

W. F. Ogden, *chairman*, Edison General Electric Appliance Company, Inc., 5600 W. Taylor Street, Chicago, Ill.
Gordon Thompson, *vice-chairman*, Electrical Testing Laboratories, 79th Street & East End Avenue, New York, N. Y.
H. E. Metz, *secretary*, Landers, Frary & Clark, New Britain, Conn.

L. F. Adams — Harold M. Potts
D. K. Blake — W. J. Russell
A. B. Craig — Carl F. Scott
Merrill DeMerit — H. P. Seelye
J. L. Hamilton — R. B. Shepard
R. E. Johnson — W. L. Tadlock
Alexander Maxwell — Frank Thornton, Jr.
L. W. McCullough — R. G. Warner
Leonard J. Moore — Wesley Weinerth

Education

Robin Beach, *chairman*, The Polytechnic Institute, 99 Livingston Street, Brooklyn, N. Y.
H. N. Walker, *vice-chairman*, The B. G. Corporation, 136 W. 52nd Street, New York, N. Y.

H. W. Bibber — J. A. Northcott, Jr.
J. M. Comly — R. G. Porter
M. S. Coover — C. A. Powel
O. E. Edison — H. C. Powell
M. C. Hughes — C. W. Ricker
E. B. Kurtz — W. F. Sims
Everett S. Lee — B. R. Teare, Jr.
W. A. Laning, Jr. — F. E. Terman
H. A. Lardner — George B. Thomas
W. A. Murray — R. W. Warner

Subcommittee Chairman

J. M. Comly, Student Guidance

Technical Committees (continued)

Electrical Machinery

F. E. Harrell, *chairman*, 1088 Ivanhoe Road, Cleveland, Ohio
J. F. Calvert, *vice-chairman*, Northwestern Technological Institute, Evanston, Ill.
W. R. Hough, *secretary*, 1088 Ivanhoe Road, Cleveland, Ohio

Sterling Beckwith	G. R. Milne
Theodore Braaten	V. M. Montsinger
J. E. Clem	T. H. Morgan
J. H. Cox	W. J. Morrill
G. T. Harness	S. H. Mortensen
C. B. Hathaway	M. S. Oldacre
A. P. Hayward	F. D. Phillips
C. C. Herskind	C. P. Potter
H. H. Kerr	W. C. Sealey
C. E. Kilbourne	B. Van Ness, Jr.
L. A. Kilgore	C. G. Veinott
C. M. Laffoon	F. J. Vogel
O. K. Marti	G. A. Waters
B. M. Werly	

Subcommittee Chairmen

C. E. Kilbourne, D-C Machinery
L. A. Kilgore, Synchronous Machinery
T. H. Morgan, Test Code Co-ordinating
M. S. Oldacre, Transformers, Induction Regulators, etc.
C. P. Potter, Induction Machinery
B. Van Ness, Jr., Insulation Resistance

Electric Welding

J. Harold Lampe, *chairman*, University of Connecticut, Storrs, Conn.

J. H. Blankenbuehler	K. L. Hansen
L. W. Clark	C. E. Heitman, Jr.
W. E. Crawford	S. M. Humphrey
J. W. Dawson	G. G. Landis
D. D. Ewing	F. W. Maxstadt
G. W. Garman	C. L. Pfeiffer
E. H. Vedder	

Electronics

S. B. Ingram, *chairman*, 463 West Street, New York, N. Y.

J. H. Cox	H. C. Rentschler
W. G. Dow	J. Slepian
K. J. Germeshausen	E. W. Schilling
T. S. Gray	B. F. Tellkamp
C. C. Herskind	H. M. Turner
O. K. Marti	D. C. Ulrey
J. E. Reid	W. C. White

Industrial Power Applications

J. J. Orr, *chairman*, United States Rubber Company, 1230 Sixth Avenue, New York, N. Y.
Herbert Speight, *vice-chairman*, Westinghouse Electric and Manufacturing Company, 40 Wall Street, New York, N. Y.
L. A. Umansky, *secretary*, General Electric Company, Schenectady, N. Y.

E. T. Carlson	J. Elmer Housley
L. W. Clark	A. E. Knowlton
W. G. Dow	E. D. Lilja
C. W. Drake	M. J. McHenry
John H. Edwards	A. C. Muir
K. K. Falk	W. A. Perry
E. Gordon Fox	Hugh L. Smith
John Grotzinger	Jerome J. Taylor
F. E. Harrell	R. L. Walsh
M. R. Horne	B. M. Werly
R. H. Wright	

Subcommittee Chairmen

D. D. Douglass, System Selection and Design
R. C. R. Schulze, Service and Switching
B. M. Werly, Substation and Feeders
K. W. John, Low Voltage Systems

Electrochemistry and Electrometallurgy

W. B. Kouwenhoven, *chairman*, Johns Hopkins University, Baltimore, Md.
J. V. Alfriend, Jr., *vice-chairman*, 225 N. Piedmont Street, Arlington, Va.
W. C. Kalb, *secretary*, National Carbon Company, Inc., Cleveland, Ohio

F. V. Andreae	T. R. Rhea
F. M. Baxandall	F. O. Schnure
L. H. Fletemeyer	W. R. Schofield
W. E. Gutzwiller	M. F. Skinker
J. Elmer Housley	N. R. Stansel
C. C. Levy	H. N. Stover
R. M. Pfalzgraff	F. J. Vogel

Subcommittee Chairmen

N. R. Stansel, Voltage Transients in Arc-Furnace Circuits
F. J. Vogel, Electric Arc Furnace Transformer Standardization

Instruments and Measurements

F. B. Silsbee, *chairman*, National Bureau of Standards, Washington, D. C.
T. S. Gray, *vice-chairman*, Massachusetts Institute of Technology, Cambridge, Mass.
C. L. Dawes, *secretary*, Harvard University, Pierce Hall, Cambridge, Mass.

A. S. Albright	I. F. Kinnard
P. A. Borden	A. E. Knowlton
A. L. Brownlee	H. C. Koenig
L. A. Bruckmyer, Jr.	Everett S. Lee
C. T. Burke	Paul MacGahan
D. T. Canfield	Whitney Matthews
E. D. Doyle	W. E. Pakala
W. N. Goodwin, Jr.	G. R. Patterson
E. I. Green	E. G. Ratz
Stanley Green	A. R. Rutter
W. T. Grumbly	Roy M. Smith
N. S. Hibshman	G. M. L. Sommerman
G. B. Hoadley	H. M. Turner
F. C. Holtz	D. A. Young
W. M. Young	

Subcommittee Chairmen

A. L. Brownlee, Dielectric Measurements in the Field
L. A. Burckmyer, Jr., Master Test Code for Temperature Measurement
D. T. Canfield, Watthour Meters
C. L. Dawes, Definitions
A. E. Knowlton, Revision of Standard No. 40
H. C. Koenig, Revision of C39
Everett S. Lee, Measurements for Industrial Control
H. M. Turner, High-frequency Measurements
W. M. Young, Master Test Code for Resistance Measurements

Marine Transportation

I. H. Osborne, *chairman*, Federal Shipbuilding and Dry Dock Company, 744 Broad St., Newark, N. J.
R. L. Witham, *vice-chairman*, Sperry Gyroscope Company, Manhattan Bridge Plaza, Brooklyn, N. Y.
W. N. Zippler, *secretary*, Gibbs and Cox, Inc., 1 Broadway, New York, N. Y.

E. C. Alger	F. C. Hoelzle
R. A. Beekman	Alex Kennedy, Jr.
H. C. Coleman	Clarence Lynn
P. J. Dumont	Fred R. Maxwell, Jr.
J. B. Feder	W. H. Reed
A. R. Gatewood	E. M. Rothen
L. M. Goldsmith	P. E. Vance
H. F. Harvey, Jr.	A. E. Waller
P. B. Harwood	F. A. Wickel
C. J. Henschel	O. A. Wilde
R. J. Wiseman	

Subcommittee Chairmen

E. C. Alger, Communications and Alarms
R. A. Beekman, Publicity, Personnel, and History
H. C. Coleman, Switchboards and Controls
H. F. Harvey, Jr., Distribution
Alex Kennedy, Jr., Power Generation
W. H. Reed, Power Application
O. A. Wilde, Fittings and Appliances
R. J. Wiseman, Wires and Cables
R. L. Witham, Navigation Equipment
W. N. Zippler, Editing

Land Transportation

A. G. Oehler, *chairman*, Simmons-Boardman Publishing Company, 30 Church St., New York, N. Y.
H. C. Griffith, *vice-chairman*, 1617 Pennsylvania Blvd., Philadelphia, Pa.
P. H. Hatch, *secretary*, 514 Siwanoy Place, Pelham Manor, N. Y.

J. C. Aydelott	Fraser Jeffrey
R. Beeuwkes	C. R. Jones
L. W. Birch	L. C. Josephs
L. N. Blugerman	Paul Lebenbaum
W. A. Brecht	F. C. Lindvall
C. M. Davis	P. A. McGee
E. B. Fitzgerald	T. H. Murphy
J. E. Gardner	J. A. Noertker
W. S. H. Hamilton	R. J. Parsons
G. L. Hoard	Dwight L. Smith
J. G. Inglis	L. J. Turley

Light, Production and Application of

E. M. Strong, *chairman*, Cornell University, Ithaca, N. Y.
W. C. Kalb, *vice-chairman*, National Carbon Company, Inc., Cleveland, Ohio
S. G. Hibben, *secretary*, The Westinghouse Lamp Division, Bloomfield, N. J.

D. W. Atwater	J. A. McDermott
Robin Beach	P. S. Millar
A. G. Dewars	T. Minasian
C. L. Dows	G. M. W. Pullen
O. W. Holden	R. C. Putnam
J. O. Kammerman	Harris Reinhardt
H. E. Mahan	I. A. Yost

Subcommittee Chairman

D. W. Atwater, Preferred Characteristics of Electric Power for Lighting

Protective Devices

T. G. LeClair, *chairman*, Commonwealth Edison Company, 72 West Adams Street, Chicago, Ill.
J. B. MacNeill, *vice-chairman*, Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa.
H. W. Collins, *secretary*, Detroit Edison Company, 2000 Second Avenue, Detroit, Mich.

A. E. Anderson	W. A. Lewis
H. D. Braley	S. C. Leyland
O. E. Charlton	H. J. Lingal
J. E. Clem	F. R. Longley
F. W. Cramer	L. R. Ludwig
William Deans	J. R. McFarlin
F. M. Defandorf	J. R. North
G. B. Dodds	H. V. Nye
W. S. Edsall	H. H. Rudd
F. R. Ford	W. J. Rudge
L. R. Gamble	H. P. St. Clair
I. W. Gross	A. H. Schirmer
H. W. Haberl	H. P. Sleeper
F. C. Hanker	C. L. Smith
E. L. Harder	F. V. Smith
R. T. Henry	Roy M. Smith
P. A. Jeanne	H. R. Stewart
L. F. Kennedy	H. E. Strang
H. E. Kent	H. R. Summerhayes
A. A. Kroneberg	J. J. Tesar
R. A. Larner	M. Towner
J. D. Wood	

Subcommittee Chairmen

J. E. Clem, Fault Current Limiting Devices
I. W. Gross, Lightning Arresters
E. L. Harder, Relays
R. T. Henry, Circuit Breakers, Switches, and Fuses

Therapeutics, Applications of Electricity to

C. V. Aggers, *chairman*, Westinghouse Electric and Manufacturing Company, X-Ray Division, 2519 Wilkins Avenue, Baltimore, Md.

Lloyd L. Call	W. B. Kouwenhoven
W. D. Coolidge	H. C. Rentschler
Roy Kegerreis	R. W. Sorensen

Technical Committees (continued)

Power Generation

A. C. Monteith, *chairman*, Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa.
A. J. Krupy, *vice-chairman*, 72 W. Adams St., Chicago, Ill.

F. A. Annett
W. L. Cisler
C. A. Corney
R. P. Crippen
J. J. Dougherty
H. A. Dryar
J. H. Foote
A. H. Frampton
R. L. Frisby
F. W. Gay
W. D. Hardaway
Fraser Jeffrey
J. A. Koontz
V. M. Marquis
C. W. Mayott
F. J. Meyer
G. M. Pollard
C. R. Reid
M. J. Steinberg
H. D. Taylor
Robert Treat

Subcommittee Chairmen

R. P. Crippen, Emergency Measures to Increase Output of Generating Systems
C. M. Laffoon, Emergency Measures to Increase Output of Generating Equipment
M. J. Steinberg, Joint AIEE-ASME Committee on Specifications for Prime Mover Speed Governors

Power Transmission and Distribution

Philip Sporn, *chairman*, American Gas and Electric Service Corporation, 30 Church Street, New York, N. Y.
H. E. Wulfing, *vice-chairman*, 72 W. Adams Street, Chicago, Ill.
I. W. Gross, *secretary*, American Gas & Electric Service Corporation, 30 Church St., New York, N. Y.

D. K. Blake
A. B. Campbell
H. E. Carson
H. A. Clark
H. W. Clark
Harold Cole
C. A. Corney

E. W. Davis
A. E. Davison
G. E. Dean
Llewellyn Evans
R. D. Evans
O. W. Gatchell
L. R. Gaty
C. M. Gilt
E. K. Huntington
J. P. Jollyman
P. R. Knapp
A. A. Kroneberg
W. A. Lewis
W. W. Lewis
J. T. Luisignan, Jr.
F. J. Meyer
Lee M. Moore
E. W. Oesterreich
W. S. Peterson
L. M. Robertson
S. J. Rosch
E. V. Sayles
A. E. Silver
D. M. Simmons
Herman Halperin
Edwin Hansson
C. A. Harrington
J. B. Hodtum
Stanley Stokes
J. J. Torok
H. M. Trueblood
C. F. Wagner
R. J. Wiseman

Subcommittee Chairmen

Harold Cole, Distribution
L. R. Gaty, Stations
W. W. Lewis, Transmissions
C. F. Wagner, General Systems

Institute Representatives

Alfred Noble Prize Committee, ASCE
H. S. Osborne

American Association for the Advancement of Science, Council
T. H. Morgan — I. Melville Stein

American Committee on Marking of Obstructions to Air Navigation
G. E. Dian — H. L. Huber

American Co-ordinating Committee on Corrosion
H. S. Phelps

American Research Committee on Grounding
C. T. Sinclair

American Standards Assoc., Standards Council
R. T. Henry — A. H. Kehoe — H. S. Osborne
Alternates
H. E. Farrer — E. B. Paxton

American Year Book, Advisory Board
H. H. Henline

Charles A. Coffin Fellowship and Research Fund Committee
Harold S. Osborne

Committee of Apparatus Makers and Users, NRC
L. F. Adams

Electrical Standards Committee, ASA
H. L. Huber — J. R. North — V. M. Montsinger
Alternates
H. E. Farrer — E. L. Moreland — E. B. Paxton

Engineering Foundation Board
F. M. Farmer — W. I. Slichter

Engineering Societies Monographs Committee
F. M. Farmer — W. I. Slichter

Engineering Societies Personnel Service, Inc.
H. H. Henline

Engineers' Council for Professional Development
O. W. Eshbach — F. Ellis Johnson — J. F. Fairman

Hoover Medal Board of Award
H. H. Barnes, Jr. — John C. Parker — F. M. Farmer

John Fritz Medal Board of Award
F. M. Farmer — David C. Prince
John C. Parker — R. W. Sorensen

Library Board, United Engineering Trustees, Inc.
W. A. Del Mar — H. H. Henline, *ex officio*
W. I. Slichter

Marston Medal Board of Award
Harry B. Gear

National Bureau of Engineering Registration, Advisory Board
C. R. Beardsley

Nat'l Fire Protection Assoc., Electrical Committee
F. V. Magalhaes — H. S. Warren, *Alternate*

National Fire Waste Council
Wills Maclachlan — Frank Thornton, Jr.

Nat'l Research Council, Division of Engineering and Industrial Research
R. W. Sorensen

Research Procedure Com., Engg. Foundation
L. W. Chubb

United Engineering Trustees, Inc.
F. M. Farmer — Everett S. Lee — C. E. Stephens

U. S. National Committee of the International Commission on Illumination
J. W. Barke — Robin Beach

U. S. National Committee of the International Electrotechnical Commission
H. L. Huber — V. M. Montsinger — J. R. North
Alternates
H. E. Farrer — E. L. Moreland — E. B. Paxton

Washington Award Commission
H. B. Gear — L. R. Mapes

Geographical District Executive Committees

District	Chairman (Vice-President, AIEE)	Secretary (District Secretary)	Chairman, District Committee on Student Activities
1 North Eastern	K. B. McEachron, General Electric Company, 100 Woodlawn Ave., Pittsfield, Mass.	R. G. Lorraine, General Electric Co., 1 River Road, Schenectady, N. Y.	A. G. Conrad, Yale University, New Haven, Conn.
2 Middle Eastern	C. A. Powel, Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa.	J. E. Treweek, Pennsylvania Power and Light Company, 117 E. Broad St., Hazleton, Pa.	R. C. Gorham, University of Pittsburgh, Pittsburgh, Pa.
3 New York City	C. R. Jones, Westinghouse Electric and Manufacturing Company, 40 Wall Street, New York, N. Y.	Roy L. Webb, Consolidated Edison Co. of New York, Inc., 4 Irving Place, New York, N. Y.	D. H. Wright, Pratt Institute, Brooklyn, N. Y.
4 Southern	J. Elmer Housley, Aluminum Co. of America, Alcoa, Tenn.	A. S. Hoefflin, Louisville Gas and Electric Co., 311 W. Chestnut St., Louisville, Ky.	E. A. Bureau, University of Kentucky, Lexington, Ky.
5 Great Lakes	A. G. Dewars, Northern States Power Company, 15 S. 5th St., Minneapolis, Minn.	N. C. Pearcy, Public Utility Engineering and Service Corporation, 231 South La Salle Street, Chicago, Ill.	H. O. Warner, University of Detroit, Detroit, Mich.
6 North Central	Arthur L. Jones, General Electric Co., P. O. Box 2331, Denver, Colo.	Murray G. Graff, General Electric Co., 650 17th St., Denver, Colo.	E. E. Clark, South Dakota State School of Mines, Rapid City, S. D.
7 South West	E. T. Mahood, Southwestern Bell Telephone Co., 11th and Oak Streets, Kansas City, Mo.	R. G. Kloeffler, Kansas State College, Manhattan, Kans.	W. F. Gray, Texas Technological College, Lubbock, Tex.
8 Pacific	Walter C. Smith, General Electric Co., 823 Russ Bldg., San Francisco, Calif.	E. M. Wright, Pacific Gas and Electric Co., 245 Market St., San Francisco, Calif.	F. W. Maxstadt, California Institute of Technology, Pasadena, Calif.
9 North West	E. W. Schilling, Montana State College, Bozeman, Mont.	Herold E. Murdock, Montana Power Company, 18 East Main Street, Bozeman, Mont.	R. E. Lindblom, University of Washington, Seattle, Wash.
10 Canada	C. A. Price, Canadian Westinghouse Co., Ltd., Sanford Ave. N., Hamilton, Ont.	John M. Somerville, Canadian Porcelain Co., Ltd., Box 428, Hamilton, Ont.	

NOTE: Each District executive committee includes also the chairmen and secretaries of all Sections within the District, and the District vice-chairman of the national membership committee.

Sections of the Institute

Name	District	When Organized	Membership Aug. 1, 1942	Chairman	Secretary	Secretary's Address
Akron	2	Aug. 12, '20	94	K. F. Sibila	A. G. Seifried	B. F. Goodrich Co., 500 S. Main St., Akron, Ohio
Alabama	4	May 22, '29	44	G. W. McCracken	M. V. Zimmerman	Commonwealth and Southern Corp., Birmingham, Ala.
Arizona	8	Mar. 22, '41	37	G. F. Maughmer	E. A. Gissel	Central Arizona Lt. & Pwr. Co., Phoenix, Ariz.
Boston	1	Feb. 13, '03	516	R. G. Porter	W. I. Middleton	Simplex Wire & Cable Co., Cambridge, Mass.
Central Indiana	5	Jan. 12, '12	133	J. R. Pies	C. R. Swenson	240 North Meridian St., Indianapolis, Ind.
Chicago	5	1893	836	J. C. Woods	E. C. Minteer	Minteer & Josler, 327 So. LaSalle St., Chicago, Ill.
Cincinnati	2	June 30, '20	214	E. F. Nuezel	F. J. Breen, Jr.	3821 Delmar Ave., Cheviot, Ohio
Cleveland	2	Sept. 27, '07	376	C. A. Harrington	D. Ramadanoff	The National Carbon Co., W. 73rd St. & N.Y.C.R.R., Cleveland, Ohio
Columbus	2	Mar. 17, '22	95	S. A. Martin	S. O. Evans	Ohio State University, Columbus, Ohio
Connecticut	1	Apr. 16, '21	333	A. G. Conrad	C. D. Hewitt	227 Church St., New Haven, Conn.
Denver	6	May 18, '15	180	H. B. Palmer	Hubert Sharp	Mountain States Tel. & Tel. Co., P. O. Box 960, Denver, Colo.
East Tennessee	4	Sept. 2, '36	145	R. A. Hopkins	B. H. McCoin	City of Knoxville Electric Dept., Knoxville, Tenn.
Erie	2	Jan. 11, '18	65	C. M. Davis	W. D. Bearce	4121 Sassafras St., Erie, Pa.
Florida	4	Jan. 28, '31	111	C. F. Titus	Joseph Weil	University of Florida, Gainesville, Fla.
Fort Wayne	5	Aug. 14, '08	93	S. D. Summers	W. W. Brooks	General Electric Co., Fort Wayne, Ind.
Georgia	4	Jan. 14, '04	119	J. M. Flanigen	Carl Evans	Electrical South, 1020 Grant Bldg., Atlanta, Ga.
Houston	7	Aug. 7, '28	133	P. H. Underwood	S. C. Commander	2615 Fannin St., Houston, Texas
Iowa	5	June 25, '29	84	L. A. Ware	W. B. Boast	Iowa State College, Ames, Iowa
Ithaca	1	Oct. 15, '02	53	H. G. Smith	A. B. Credle	Cornell University, Franklin Hall, Ithaca, N. Y.
Kansas City	7	Apr. 14, '16	137	C. G. Roush	C. M. Lytle	P. O. Box 679, Kansas City, Mo.
Lehigh Valley	2	Apr. 16, '21	188	E. R. Beers	L. Z. Ludorf	Penn. Power and Light Co., 135 N. Washington St., Wilkes-Barre, Pa.
Los Angeles	8	May 19, '08	540	T. M. Blakeslee	P. L. Johnson	Box 5300, Metropolitan Station, Los Angeles, Calif.
Louisville	4	Oct. 15, '26	73	M. M. Hughes	L. G. Weiser	Westinghouse Electric & Mfg. Co., 1618 Heyburn Bldg., Louisville, Ky.
Lynn	1	Aug. 22, '11	186	J. H. Goss	M. S. Wilson	General Electric Co., Factory 2nd L., West Lynn, Mass.
Madison	5	Jan. 8, '09	73	R. R. Knoff	E. J. Van Duesen	2702 Sommers Ave., Madison Wis.
Mansfield	2	Mar. 6, '39	71	H. O. Whiteley	J. M. Robinson	North Electric Mfg. Co., Galion, Ohio
Maryland	2	Dec. 16, '04	322	H. J. Casey	B. Van Ness	1503 Lexington Bldg., Baltimore, Md.
Memphis	4	May 23, '30	56	J. P. Argo	Herman Leightman	Memphis Light, Gas and Water Div., 179 Madison Ave., Memphis, Tenn.
Mexico	3	June 29, '22	53	G. Robles	J. Rosas	Mexican Lt. & Pwr. Co., Ltd., Gante No. 20, Mexico, D.F. Mexico
Michigan	5	Jan. 13, '11	418	M. B. Stout	J. W. Bishop	134 Englewood Ave, Detroit, Mich.
Milwaukee	5	Feb. 11, '10	313	F. W. Bush	T. B. Jochem	Cutler-Hammer, Inc., 315 N. 12th St., Milwaukee, Wis.
Minnesota	5	Apr. 7, '02	98	Wm. Endicott	C. W. Lethert	Northern States Power Co., 15 So. 5th St., Minneapolis, Minn.
Montana	9	June 24, '31	45	D. K. Brake	C. R. Davis	Montana Power Co., Butte, Montana
Muscle Shoals	4	Feb. 18, '38	33	R. C. Fuller	S. J. Wolfenson	T.V.A., Project W3, Wilson Dam, Ala.
Nebraska	6	Jan. 21, '25	59	J. M. Gibb	I. M. Ellestad	Northwestern Bell Telephone Co., Omaha, Nebr.
New Mexico-West Texas	7	Mar. 7, '40	43	F. A. Decker	L. R. Hammond	Phelps Dodge Corp., El Paso, Texas
New Orleans	4	Dec. 8, '33	133	J. V. Hay	F. E. Johnson	317 Baronne St., New Orleans, La.
New York	3	Dec. 10, '19	3,447	C. C. Whipple	M. D. Hooven	Public Service Electric & Gas Co., 80 Park Pl., Newark, N. J.
Niagara Frontier	1	Feb. 10, '25	198	J. F. Oehler	E. R. Paige	Buffalo Niagara Electric Corp., Buffalo, N. Y.
North Carolina	4	Mar. 21, '29	107	E. E. Kilburn	A. L. Humphrey	Tide Water Power Co., Warsaw, N. C.
North Texas	7	May 18, '28	170	T. D. Thomas	H. G. Mathewson	Southwestern Bell Telephone Co., Dallas, Texas
Oklahoma City	7	Feb. 16, '22	104	Ralph Randall	C. L. Jobe	Oklahoma Gas & Elec. Co., Oklahoma City, Okla.
Philadelphia	2	Feb. 18, '03	809	G. W. Bower	A. C. Muir	1138 Commercial Trust Bldg., Philadelphia, Pa.
Pittsburgh	2	Oct. 13, '02	662	B. M. Jones	G. W. Penney	Westinghouse Electric & Mfg. Co., E. Pittsburgh, Pa.
Pittsfield	1	Mar. 25, '04	194	C. W. Germeck	W. S. Fielding	General Electric Co., 100 Woodlawn Ave., Pittsfield, Mass.
Portland	9	May 18, '09	196	C. E. Canada	A. O. Mangold	Northwestern Electric Co., 920 S.W. Sixth Ave., Portland, Ore.
Providence	1	Mar. 12, '20	100	D. W. Alden	G. E. Andrews	40 Bridgham St., Providence, R. I.
Rochester	1	Oct. 9, '14	112	R. A. Whitford	J. H. Rogers	262 Albemarle St., Rochester, N. Y.
St. Louis	7	Jan. 14, '03	361	I. T. Monseth	O. T. Farry	Wagner Electric Corp., 6400 Plymouth Ave., St. Louis, Mo.
San Diego	8	Jan. 18, '39	54	B. B. Gravitt	W. J. Kenline	3491 Cooper St., San Diego, Calif.
San Francisco	8	Dec. 23, '04	549	B. L. Robertson	G. C. Tenney	68 Post St., San Francisco, Calif.
Saskatchewan	10	Oct. 14, '25	8	M. L. Haynes	J. R. Young	1945 Scarth St., Regina, Sask, Can.
Schenectady	1	Jan. 26, '03	559	T. M. Linville	P. H. Light	General Electric Co., Central Station Dept., Schenectady, N. Y.
Seattle	9	Jan. 19, '04	230	L. D. Snow	H. M. Gustafson	General Elec. Co., 1290 Dexter Horton Bldg., Seattle, Wash.
Sharon	2	Dec. 11, '25	153	W. L. Teague	H. S. Gates	1583 McDowell St., Sharon, Pa.
South Bend	5	Feb. 26, '41	58	J. A. Northcott, Jr.	H. E. Ellithorn	417 Parkovash Ave., South Bend, Indiana
South Carolina	4	Mar. 2, '40	53	F. W. Chapman	W. H. Kendrick	South Carolina Electric & Gas Co., Columbia, S. C.
South Texas	7	May 23, '30	53	W. F. Pinckert	G. E. Schmitt	Lower Colorado River Authority, Austin, Texas
Spokane	9	Feb. 14, '13	82	H. J. Reeves	R. C. Kelly	Washington Water Power Co., 825 W. Trent Ave., Spokane, Wash.
Springfield	1	June 29, '22	52	Isaiah Creaser	L. P. Kongsted	American Bosch Corp., Springfield, Mass.
Syracuse	1	Aug. 12, '20	119	S. C. Osborne	M. H. Pratt	Central N. Y. Power Corp., 300 Erie Blvd., W., Syracuse, N. Y.
Toledo	2	June 3, '07	89	W. C. Champe	W. M. Campbell	2145 Central Grove Ave., Toledo, Ohio
Toronto	10	Sept. 30, '03	396	D. W. Callander	T. C. D. Churchill	76 Adelaide St., West, Toronto, Ont., Canada
Tulsa	7	Oct. 1, '37	87	O. A. Haas	H. A. Norberg	Nelson Electric Mfg. Co., 219 N. Detroit, Tulsa, Okla.
Urbana	5	Nov. 25, '02	78	M. A. Faucett	W. E. Miller	University of Illinois, Urbana, Ill.
Utah	9	Mar. 9, '17	64	Wm. N. Grooms	J. A. McDonald	General Electric Co., P. O. Box 779, Salt Lake City, Utah
Vancouver	10	Aug. 22, '11	95	T. Ingledow	F. V. Knight	1796 W. 15th Ave., Vancouver, B. C., Can.
Virginia	4	May 19, '22	150	E. S. Fitz	W. A. Murray	Virginia Poly. Inst., Blacksburg, Va.
Washington	2	Apr. 9, '03	600	G. R. Wilhelm	F. S. Black	Potomac Electric Power Co., 10th and E Sts., N.W., Washington, D. C.
West Virginia	2	Apr. 9, '40	39	E. D. Knight	R. C. Hoffman	Appalachian Electric Power Co., Charleston, W. Va.
Wichita	7	Sept. 16, '37	57	J. F. Huff	R. F. Dice	Kansas Gas and Electric Co., Wichita, Kans.
Worcester	1	Feb. 18, '20	63	W. W. Locke, Jr.	T. R. Holton	American Steel & Wire Co., Worcester, Mass.
